dict with respect to the merits of the two races of Gladioli as represented by the flowers exhibited was that whilst the Nanceianus varieties were first in interest, they fell a long way behind the Gandavensis race in point of form, size and richness of color in the flowers.

It would be difficult to find in the whole range of the great Irid order any flowers equal in richness and beauty to such Gladioli as Leonard Kelway, Mont Blanc, Baroness Burdet

Fig. 59.—*Rosa Watsoniana*.—See page 476.

having been raised by Monsieur Lemoine, of Nancy, and distributed last year. The Royal Horticultural Society had invited Monsieur Lemoine and Mr. Kelway, the famous grower of the Gandavensis race, to read papers on, and make an exhibition of, these two races of Gladioli. The result was a most interesting and edifying exhibition of beautiful flowers, and the production of two papers of the greatest value and importance to cultivators of the Gladiolus. The general ver-

Coutts, Baron Schroeder or even than Gandavensis itself. Spikes as thick as a man's thumb, bearing about two feet of flowers, of which twelve or more are open at the same time, are common with Gladiolus growers now. Twenty years ago the spikes of the best kinds were not nearly so stout, and four or six flowers open at once were considered good. Mr. Kelway, Messrs. Burrell & Sons, of Cambridge, and one or two other growers are to be thanked for the great improvement

made not only in the size and color of the flowers, but also in the vigor of constitution which characterizes many of the newer kinds.

Mr. Kelway stated that he had grown and bred Gladioli for nearly sixty years, but it was not until 1857 that he took up their cultivation and improvement in earnest. His cultural directions were simple: a light, deep soil, the ground to be roughly dug and manured in October and allowed to remain thus till February, when the manure should be turned in and the corms planted about three inches deep, eight inches apart in the row and eighteen inches between each row. They should be lifted soon after the flowers fade and before the leaves turn yellow. They are less satisfactory if allowed to remain in the ground longer than this. They should be dried in the sun and afterward stored in a dry, cool room or shed for the winter.

By selecting the kinds and planting the bulbs in succession Mr. Kelway has these plants in flower from July till November. For decorative purposes the flowers are of great value. A large vase filled with the huge spikes of bright colored flowers is a delightful picture, and the flowers remain good for a fortnight or more. Mr. Kelway's exhibits of Gladioli at the London and provincial shows invariably open people's eyes. Yet the plants are not much grown, notwithstanding the small amount of trouble they give. Most inexperienced growers here fail with Gladioli through mistakes in harvesting and storing the bulbs.

The Nanceianus varieties possess the useful characters of hardiness and a preference for remaining in the ground undisturbed from year to year. A celebrated grower stated at the meeting that he had had some of Lemoine's hybrids (Lemoinei) undisturbed in the ground from six to eight years, and that where one bulb was at the time of planting there is a large clump now. Unquestionably we have in them the foundation of a most valuable race of garden plants. They are only beginnings as yet, but unless they differ in this respect from the Gandavensis varieties a few more years will work a great improvement. The history of his hybrid Gladioli, as told by Monsieur Lemoine himself, is most interesting. He started in 1875 with *G. purpureo-auratus*, a species brought from Natal to England in 1870. This has a spike two to three feet high, arched above, the flowers small, cupped, and colored dull yellow, with a blotch of purple on the lower segment. It proved perfectly hardy in England, and increased rapidly if left in the ground. Lemoine crossed it with the hybrid *G. Gandavensis*, which had been raised from *G. psittacinus* and *G. cardinalis*. From this cross he obtained Victor Lemoine and Marie Lemoine, the former with salmon-pink, the latter cream-yellow flowers. These obtained first-class certificates, and were distributed in 1880. The largeness of flower and number on a spike of Gandavensis had yet to be infused into the new race, so the first hybrids were crossed with it again, and every year about ten new varieties were thus obtained, until altogether sixty of them, distinct in form and color, and showing considerable variety in both these characters, had been named and distributed. The consanguinity of the whole of these was always apparent, the cupped flower, and a dark blotch surrounded by a clear space of yellow on the lower segment, being characteristic of them all. Colors of every shade, from yellow to purple, and blended in the most remarkable manner, had been the outcome of crossing a dull yellow-flowered species with the scarlet-flowered *G. Gandavensis*. So far the hybrids are known as *G. Lemoinei*. Then M. Lemoine began with *G. Saundersii*, introduced from the Cape, and flowered for the first time at Kew in 1877. It is figured in the *Botanical Magazine*, t. 5873. This species is remarkable for its short, curved, somewhat slender spike, bearing a few large flowers which have reflexed segments, and colored pale scarlet, white and pink. It is quite as hardy as *G. purpureo-auratus*. In 1882 Max Leichtlin crossed *G. Gandavensis* with *G. Saundersii*, which resulted in seedlings with stout spikes, large open flowers, fully four inches across, and showing considerable variety of color. These are supposed to have been secured by an American nurseryman, and it is possible that they or their progeny are the fine seedlings from Messrs. Hallock & Son, noted by me a week or two ago as being in flower at Kew.

Monsieur Lemoine crossed *G. Saundersii* with some of the best of the varieties of *G. Lemoinei* in 1883. When *G. Saundersii* was the seed-parent very few seeds were obtained, and from them came the two large-flowered, richly colored seedlings known as President Carnot and Maurice de Vilmorin. When one of the seedlings of *G. Lemoinei* was pollinated from *G. Saundersii* there were plenty of seeds. Thus the new race known as Nanceianus was originated, and in 1889 nine of the seedlings were named and distributed, whilst a large number of seed-

lings have not yet been sent out. The king of the lot is that called President Carnot. Its spikes are six feet high, the flowers seven inches across, the segments spreading and open, whilst the color is cherry-red, striped with carmine, the lower segment having a large scarlet blotch surrounded by a band of white.

Monsieur Lemoine claims for his new seedlings a hardier and better constitution than that of *L. Gandavensis*. They thrive in almost any kind of soil and do not require lifting in autumn; they are not influenced by unfavorable seasons to the same extent as *L. Gandavensis*. They bear and invite close inspection; the more one examines them the more beautiful they appear, and they show a wonderful range of color.

Of the seedlings shown by Monsieur Lemoine the following were the most noteworthy:

BAUDIN, flowers large, scarlet, with a yellow blotch and crimson throat.

M. DE VILMORIN, purplish lavender, flaked with brick red and yellow.

NEUE BLEUE, flowers deep violet, blackish purple in the throat; they were one and a half inches across. This was the most striking novelty exhibited, being almost blue in color.

E. V. HALLOCK, flowers large and open, colored cream-yellow, with a blotch of rich maroon on the lower segment.

CROZY FILS, bright crimson, white toward the base and lined with white.

M. LEFEBVRE, large flowers, colored raspberry red, speckled with crimson and blotched with white.

ALICE WILSON, bluish white, flaked and blotched with crimson; a very good variety.

MASQUE DE FER, flowers small, the four outer segments colored blood crimson, the inner pair smaller and deeper in color.

PACTOLE, sulphur yellow, darker in the throat, with a crimson blotch.

It may be said of these seedlings originated by Monsieur Lemoine that their most striking feature is the richness and extraordinary shades of color they show, and he is to be congratulated on what he has accomplished with this race of plants in so short a time.

Cultural Department.

Bulbs for the Greenhouse.

Scilla Clusii, now offered in quantity, is a really desirable winter-flowering bulb. We have cultivated it for the past three years, and have found that the bulbs may be had in flower from Christmas onward by starting them in succession. *S. Clusii* is, I believe, a native of Algeria, and, like all bulbs from that region, is not hardy, but succeeds well in an ordinary greenhouse or with window culture. A good-sized flowering bulb will need a six-inch pot and an abundance of water when about to flower. *S. Clusii* seeds freely, and, what is of more importance, the seeds germinate readily and make strong flowering bulbs the second or third year if treated liberally.

S. Peruviana resembles the above in many respects, except that it is a giant by comparison. This is not a South American plant at all, but is a native of south Europe. It is generally hardy in English gardens, but not so here in the eastern states, though it is a pity, for the immense pyramidal heads of bright blue flowers are very ornamental together with the thick, broad green leaves, which form a fine setting for the spike of flowers. *S. Peruviana*, however, has one fault that may tell against it in the opinion of many cultivators—that is, it never flowers two years in succession; it seems to need a whole year's rest after the effort of producing its large spike of flowers.

Ornithogalum Arabicum is another bulb which we have grown for several years, and which has been recently distributed in quantity. When one can get this plant in flower, it is the best of the genus. The flowers are large, pure white, with a dark olive-green centre, usually described as black. This plant has the same fault as that of the *Scilla* above referred to—it is impossible to flower it annually. We have grown some thirty bulbs, and every second year all that were large enough produced fine spikes of flowers, and just as surely did we never get a flower the year after. This is the more remarkable as the bulbs, many of them, were the offsets formed from the older bulbs and grown on. Had they been all of the same age or obtained at the same time it would not be surprising; but it appears that, under cultivation at least, it is the nature of the plant to abstain from flowering every second

year, and therefore those who have *O. Arabicum* should not throw it away because it did not flower last year, or if it did and fails to do so this coming season. All who know it will be perfectly willing to wait until the second year, for the plant has a distinct beauty peculiarly its own. These bulbs should all be potted in rich soil with good drainage and plenty of water when the flower stems appear. In all three of the plants named the leaves appear too weak to bear their own weight; they fall down over the pots and split in the centre if not supported by a cord tied to stakes around the edge of the pots or in some other way. There are white forms of both *Scilla Clusii* and *S. Peruviana*, but in each case the typical blue is the most desirable.

Last year I spoke of the value of *Oxalis Bowiei* for pot culture, and many inquiries were received at the time as to where the plant could be obtained and when to plant it. This is the best time to pot the bulbs, and they will start to grow at once and flower until Christmas. There seems to be a general waking up to the value of this *Oxalis*, which is the showiest and best of a genus that contains some 200 species.

The so-called *K. australis* is not now recognized as a species by some of the leading botanists, who claim that it is merely a form of *K. Belmoreana*, though it is still catalogued by some European growers as *K. australis*. The Kentias have become very popular of late years, and are now grown by thousands in the larger nurseries throughout the Atlantic states, while the seeds are imported direct and by the bushel. The Palm-seed trade, by the way, has attained large proportions now, but the limit will probably be reached in a few years, as the number of seed-growers appears to be increasing more rapidly than the demand, large as this has been.

Geonoma gracilis is a very pretty little Palm and useful for occasional decorations, though for lasting qualities under adverse conditions it is not to be compared with *Cocos Weddelliana*, which has much tougher foliage, and is therefore much more extensively used on this side of the ocean. To be kept in good condition *G. gracilis* should be well shaded, but at the same time free ventilation is necessary, else the foliage will be too soft. The same rule, as to shade, applies to all the *Geonomas*, because in their natural condition they are usually

A Stone Bridge in Wales.—See page 475.

There is a good colored plate of this plant in the London *Garden* of May 31st of this year, under the name of *O. Bowiciana*. In England this plant is used for summer flowering, but the bulbs are usually shipped to this country in fall with other bulbs from Holland, and make equally good winter pot-plants. The foliage resembles gigantic Shamrocks, and the flowers are one and a half inches across and of a bright rose color. *O. Bowiei* is well adapted to window culture, and multiplies rapidly by means of its bulbs.

South Lancaster, Mass.

E. O. O.

Palm Notes.

PROMINENT among the Palms for conservatories, and useful as well for house decoration, are the Kentias, the varieties most in use being *K. Forsteriana*, *K. Belmoreana* and *K. Canterburyana*, all of which are decorative plants of the first grade. These Palms all succeed admirably under cool-house treatment, although the first two sorts mentioned are used in much larger quantities than *K. Canterburyana*, the latter being a much slower grower, and, consequently, not nearly so profitable a plant to commercial growers.

found growing beneath the shade of other and larger growing Palms, and seldom or never out in the open.

Some of the "Fish-tail Palms" or *Caryotas* are very useful and highly ornamental as small and medium sized plants, though they rapidly attain such proportions, when under suitable treatment, that they are not suited for all collections. Of the *Caryotas* the most common and easiest to procure are *C. urens* and *C. sobolifera*, both of which are good and also easy to manage, as they germinate from seed readily and in a short time and make rapid growth.

Caryota urens throws up its handsome leaves on strong stems, and in a large plant they sometimes reach a length of twelve feet or more. The leaves are bipinnate, which is an unusual characteristic among Palms, and the pinnules are more or less wedge-shaped, being from six to eight inches in length and about half that measurement in width. The ends of the pinnules are erose, this giving them an odd appearance and readily suggesting the common appellation of "Fish-tail Palm," while the color of the leaf is dark green. Another peculiarity of *C. urens* is the manner in which it flowers, though this process does not begin until the plant has attained its full size. It begins to flower from the centre at the top of the

stem, after which the flower-spikes are produced in succession downward nearly to the base of the trunk, until the vitality of the plant is exhausted. The seeds are somewhat larger than a Bush Bean, dark brown in color and quite hard, this description applying to the seed proper after the outer fleshy rind has been removed.

C. sobolifera is also a fine plant, and is more dwarf in growth than the preceding. It also has bipinnate leaves, which are bright green in color, and as it throws up suckers at the base of the plant it naturally has a more bushy habit than *C. urens*. Other good representatives of this genus are *C. furfuracea* and *C. Rumphiana*, both of which are good decorative Palms. *Acanthorrhiza stauracantha*, sometimes known as *Chamærops stauracantha*, is another fine Palm which will succeed in a moderate temperature. It has palmate leaves, deeply divided, and dark green above, while the under side is covered with a silvery tomentum. A distinguishing feature of this plant is the mass of root-like spines which surround its base, and from which its generic name is derived. It is a native of Mexico, and though not yet very common, has been in cultivation for many years.

A few Sabals prove very useful in a collection of plants, as they will endure much hard usage with but little apparent injury, their deeply divided, flabelliform leaves being of very strong texture, so that they stand well when bedded out in the summer. *S. Adansonii*, which is found in some of the southern states, and *S. Blackburniana*, a native of the West Indies, are among the best and most serviceable.

Holmesburg, Pa.

W. H. Taplin.

The Water-Garden.

NYMPHÆAS and other flowers are still blooming in the tank, but cool nights are checking rampant growth, and the frost will soon close an aquatic season which has been full of interest. The plants under culture have usually grown freely, though there are some failures which are rather puzzling. Sometimes, for instance, a Nymphæa, in apparent good health and well planted, has remained stationary for weeks, and then shot suddenly into vigor. Again, one would like to know to what extent the coloring of the flowers is affected by the manure used, as this would seem to be so affected in the case of the pink Lilies. In my small tank it is necessary to restrain the plants somewhat by contracting the root-room, the disadvantage of which is that the gross feeders use up the nutriment very effectually before the end of the season. Perhaps the addition of bones in a rather coarse shape or some other slowly decomposing fertilizer would prove a useful addition to the barnyard manure usually recommended? Of course, the plants are generally inaccessible, so that necessary stimulants cannot be applied at will.

There is often a question as to whether a small tank does not become stagnant, but with vigorous vegetation and a supply of fish there should be no trouble on this score, though a water-garden is no more automatic than any other and requires a certain amount of intelligent attention. Since the settlement of the manure early in the season the water has remained perfectly clear, and while, perhaps, not potable, it has been free from low forms of vegetation and has bred no mosquitoes; though the fish, finding nice spawning grounds in the sand, have multiplied exceedingly and added abounding life to the water. Ordinary gold fish are hardy and attractive, but a few Chinese Fantails must give a new interest to this department another season. Of the white Nymphæas, *N. alba candidissima* has proved the sturdiest grower and most persistent bloomer. The flower is larger than that of *N. odorata*, though without its fragrance. *N. pygmæa alba*, the little Chinese hardy variety, is also still in bloom, with no sign of going to rest. This Water Lily is rather inconspicuous in a pond, but very pretty in a small tank, in-doors or out.

Of the colored Nymphæas, *N. Devoniensis*, with its noble deep rose colored flowers and rich wine colored leaves, is probably the most beautiful, and, though blooming at night, it should be in every collection. Another tender kind and a more free bloomer is *N. Zanzibarensis*, which has bloomed continuously since early summer. Its large purple flowers, borne well above the water, are very attractive. The red variety is plentiful, though some stir seems to have been made over one of this color said to have been raised in Germany this year. Seedlings of the Zanzibar Water Lily are rather inclined to sport through shades of red and purple, though the dark purple is a somewhat scarce plant. Cape Cod Lilies, in a rich compost, were very highly colored during an altogether too short season.

The French *N. rosacea* seems to be different from this

only in having a much more delicate pink tint. *N. chromatella* has shown numerous large flowers of a rich yellow tint, with deeper colored stamens. This bears the largest flowers of any yellow variety, some blooms nearly approaching those of *N. candidissima* in size. The leaves are very distinct, being blotched above and thickly spotted below with red. *N. sulfurea*, another of Marliac's hardy Lilies, was even more brightly spotted, but has yet not flowered. *N. Mexicana*, for which I am indebted to Mr. Horsford, also refused to move for me, but, as shown by Mr. Wm. Tricker, is a smaller flower than *N. chromatella*, though of a fine yellow. As it has a slightly mottled leaf and the habit of *N. flava*—of throwing out runners—it is probably near akin to that variety, if not identical. It is to be hoped that collectors and fanciers will search carefully for fine or distinct forms of our native Nymphæas, for no doubt, with care, such may be found.

No collection of aquatics is complete without *Nelumbium speciosum*, for the introduction of which we owe a great debt to Mr. Sturtevant. Of this one does not know whether to admire most the noble flowers or the wonderful, beautiful leaves. It is a plant of vigorous growth, and needs restraint, or its runners will quickly fill a large space. It is still throwing up its flower-buds. But for vigorous growing aquatics commend me to *Eichhornia (Pontederia) crassipes* (South American Pond-weed). The note in GARDEN AND FOREST as to this growing in acre plots was no "traveler's tale," as it will rapidly fill all available space. It will increase about 500 per cent. under ordinary culture, and whether planted in the ground or floating in water it is a vegetable wonder with beautiful flowers. *Limncharis Humboldtii*, with its fine yellow flowers, of course, is ever attractive. Two neat little floaters are Azolla, with small oval leaves, and *Salvinia natans*, a little Selaginella-like plant of rapid increase.

Of the Sagittarias, *S. Japonica* has the finest flowers, in racemes of pure white, very double and Balsam-like. *S. Montevidensis* is the strongest grower of the race, with broad, deep green, tall foliage, and large, white, single flowers, with a crimson spot at base of each petal. Not the least attractive and satisfactory plant is *Cyperus Antiquorum*, always exciting attention by its distinctness, and of sturdy, vigorous habit. The Swamp Plantain (*Alisma Plantago*) is an attractive and showy plant, with its large, loose raceme of small white flowers. It seems to be beloved of aphides, which, however, soon disappear if the plants are sprayed or syringed with pure water forcibly enough to wash them off, when the fish quickly dispose of them.

Elizabeth, N. J.

J. N. Gerard.

Bulbs from the Pacific Coast.

MANY of the species of *Calochortus* and *Brodiaea* from the Pacific Coast, especially those from California, are somewhat difficult to manage in our cold eastern climate. The ocean currents of that coast have such an influence on the climate that even in the northern portions of Washington along the coast the winters are quite mild as compared with the same season farther east. Some of these bulbs when wintered in an ordinary cellar begin to grow about the last of February, and by the time the ground is ready for them in spring this early growth has so exhausted them that they have little vigor left. They are not hardy, and if planted in autumn without protection will not survive our severe winters. Perhaps a very cool cellar might prevent this winter growth, but I question it. The only way I have been able to flower many of them has been to plant early in autumn and protect with three or four inches of leaves. If planted before the weather is too cold they become well rooted before winter. I believe that most of them will bear some freezing, and it seems to me that it is the alternate thawing and freezing of plants that winter kills so many. If they can be kept from thawing before spring after they have once been frozen, the cold is not so injurious. By covering them with three or four inches of leaves, though not enough to keep out all frost, they will remain frozen and dormant until it is time to remove the covering in spring.

Mexican bulbs are quite different in their manner of growth, and may be wintered in a cellar with perfect success. They will not usually start to grow before the last of May or first of June, even if planted as early as the ground can be prepared in spring. The Fritillaries from California and Oregon have done much better planted in autumn and treated in this way; and the Lilies, though much more hardy than the other bulbs, seem to do better when covered. No doubt deep planting may answer for some of them, but if the soil is of the right kind I would prefer to plant five or six inches deep, with a light covering, to eight or ten inches.

Most early-flowering plants, if not all of them, should be planted early the previous autumn. August, or July even, is not too early for some of them. The Dog's-tooth Violets, Chionodoxas, Spring Beauties, Trilliums, etc., are never as strong the first season when planted in spring or late autumn as when set in August and September. They do not flower so early nor last so long.

The Lilies from the Pacific coast are most of them early bloomers, and should be planted in early autumn. We have seldom succeeded in flowering *L. Washingtonianum* or *L. Humboldtii* when planted in spring, and they seem to require more time to become established than most plants. *L. pardalinum* has been the hardiest species. In a light loamy soil *L. parvum* and *L. rubescens* do finely, but in clay or clay loam they refuse to thrive. *L. Parryi* is a more southern species, yet it seems hardy with deep planting, and is not hard to grow. Its beautiful canary-yellow flowers appear with those of the earlier flowering sorts. It needs more moisture, however, than the other species.

Southwick, Mass.

F. H. Horsford.

The Celery Blight.

THIS season has been particularly favorable for the development of the leaf-blight of the Celery. In a recent ride through portions of Mercer County, New Jersey, gardens were found where the Celery crop was practically a failure—the plants almost from the time they were set in the benches having suffered from the blight. This unfortunate state of the plants is due primarily to a parasitic Fungus called *Cercospora Apii*, that infests the Celery and some allied plants, the Carrot often suffering considerably from the same disease.

The presence of the blight is evidenced by yellowish green irregular patches upon the foliage. These spots shortly turn to a brown color, and finally the entire leaf, in the worst cases, droops, dries up and dies. If one of the diseased patches was examined under the microscope it would be found that small brown tufts of minute filaments protruded from nearly every one of the thousands of breathing pores in each square inch of the epidermis. Upon the tips of the threads constituting the tuft are borne long, slender spores, which fall away when ripe, and are carried about by the winds when dry and by the rains during wet weather. As the feeding threads of the Fungus are throughout the substance of the infested plant before they come to the surface to bear their spores, it is useless to try and effect a cure of foliage already badly infested.

The most natural thing to do is to pick off the worse than worthless leaves and burn them. This will do something to hold the trouble in check. In the second place, some substance can be placed upon the diseased parts to kill the spores, and at the same time upon the healthy plants or parts of plants to prevent the germination of the spores that may lodge there. From the nature of the trouble and a knowledge of what certain chemicals have done with other parasitic Fungi, it is reasonable to conclude that the compound of cupric carbonate in ammonia would prove a great assistance in ridding truck-farms of this serious pest. The formula for the Grape-rot found most effective is, three ounces of the copper carbonate in one quart of ammonia and diluted to twenty-two gallons with water.

It is a well known fact that some varieties of Celery are less susceptible than others—the "White Plume" has an excellent record, as being comparatively free from the disease.

The recent heavy rains that have fallen throughout the country will prove a great blessing to the Celery crop. They will infuse new vigor into the plants and at the same time check the growth of the blight for awhile, for it seems to be a lover of dry weather. Shading the young plants with lath or boards high above the rows has sometimes saved the crop.

Among allied plants the Carrot is the one most susceptible to this blight. A variety of the same species is found upon the Parsnip, and an abundance of wild Carrot and Parsnip in a region may be propagating places for the Celery blight.

Rutgers College.

Byron D. Halsted.

Planting Daffodils.—The time for this work is at hand, and the question arises, How deep ought they to be planted? First-rate authorities on this subject advise shallower planting than I have found desirable, recommending in general a depth of four inches from the crown of the bulbs to the surface of the soil, but, of course, allowing a difference for the size and kind. It must be remembered, however, that this refers to bulbs which are lifted and transplanted every year, and this makes a great difference. Where bulbs are to be left for several years without being moved, I am inclined to think

that deeper planting is better—quite twice as deep as that above mentioned.

No one should venture to lay down an absolute rule on such a subject, as soil makes a great difference, and experience is the best guide in every garden. But I find that in this deep and retentive soil, shallow planting produces a tendency to multiply rapidly, to the deterioration of the size of the bulb and the flower. I have certainly noticed, in beds of wild Daffodils, that when I have selected an individual of extra large flower and growth, the bulb is deeper than average, and larger if reached. I have found the same rule hold in my garden. Newly purchased bulbs, if fine and well ripened, will the first year produce equally good flowers, if planted in good soil, whether planted deep or shallow. To judge of the respective merits of deep and shallow planting, the second and third flowering season must be waited for; and I should recommend those who wish to decide between the merits of the different depths to divide a dozen similar bulbs, planting in the same border and soil, half at a depth of nine inches and half at a depth of four, and, having labeled them carefully, without disturbing them in the interval, to let us know the result when they are in flower in 1893.—C. Wolley Dod, in *Gardeners' Chronicle*.

Aster Novæ Angliæ.—This is one of the handsomest species of the large genus the greater portion of which are natives of North America. Novices are often puzzled to know which of the many kinds catalogued are good and distinct varieties for garden decoration. This is the less surprising since enterprising nurserymen advertise well known species under names which Professor Gray never heard of. The New England Aster is by no means peculiar to the eastern states, for we are told it is found from Canada and Saskatchewan to South Carolina and Colorado; it is one of our best tall-growing plants and never fails to give an abundance of bloom in the autumn months. In the back rows of large borders, and when used in conjunction with other tall-growing plants, such as *Helianthus orgyalis*, it is very effective. The variety *Roseus* has rays as large as the type, and of a deep shade of rose that is very pretty in contrast with the blue of the species. One thing more needs to be said of this class of hardy plants that form great clumps in the border, which is: that one should never hesitate to divide them when they have become large. This should be done directly after the flowering season is past, or, better still, in spring, before growth commences. The clumps may be carefully broken up and replanted in the same place, provided a liberal quantity of manure is placed beneath them. This should not be allowed to come in contact with the roots, but should be first covered with soil, upon which the plants may be set. A healthy and deep root action will thus be ensured, and any check to growth in a dry season be prevented.

South Lancaster, Mass.

O.

Inula grandiflora.—In reply to Mr. E. O. Orpet's queries, I beg to state that seeds of this plant were received from the Himalayas through the liberality of Dr. King, at Calcutta, under the designation "Composite, species." I called it "grandiflora" in accordance with a suggestion from Sir J. D. Hooker when describing *I. Hookeri*. It may, however, turn out to be an entirely new species. In any case it is a very showy and easily cultivated perennial.

Delphinium Zalil is a native of Afghanistan and was sent to Europe by Dr. Aitchison. It flowered here two years ago, and is a showy annual or biennial, the average height here being two feet. The flowers in its native haunts are used as a dye for leather. The coriaceous, fleshy roots are often exhausted the very first year by abundant flowering, and never keep longer than two years.

Ostrowskya magnifica, perhaps, may not be quite hardy in the northern states of America. I lost several hundred last winter, when the frost was not serious. It is a gorgeous plant and well worth all the care it requires. The seed very soon loses its power of germination, and should be sown a few weeks after it ripens.

Baden-Baden.

Max Leichtlin.

Japanese Anemones.—These plants have been so often commended for autumn display that it almost seems superfluous to refer to them again. They are especially welcome at this season of the year, when few plants are in bloom in the borders, which unavoidably have now a ragged appearance. They make excellent pot plants; specimens with over a hundred blooms open at once, in twelve-inch pots, are very striking. The length of time they remain in bloom, four to six weeks, still further recommends them. Their culture is very

easy. Good loam, yearly repotting and liquid manure when forming the flowering stems; these seem to be all the requirements necessary to insure success; yet, we seldom see them well grown.

Wellesley, Mass.

T. D. H.

Clematis paniculata.—For a vigorous growing, profuse flowering species this cannot be excelled. The long shoots of this plant, now in bloom, are furnished with crowded clusters of feathery, fragrant, white flowers, which, though small, are borne in such wild profusion that the vine appears as a mass of white. The lower vine is well furnished with large, firm leaves. A Clematis which will make eight or ten feet of vigorous growth in its first season, is free from disease and flowers so profusely, is an ornament to any garden.

Correspondence.

Home Experimental Gardens.

To the Editor of GARDEN AND FOREST:

Sir.—The value of experimental stations varies according to the good judgment of the Director and the wide diffusion of results in an intelligent form. I believe, however, that, as a rule, we get as reliable reports to guide general cultivation from private experimenters. I have in a long course of trials learned to rely on one or two special sources of information in each special field of work. If I wish to know the truth about a new Strawberry I compare the judgment of such men as Crawford, Williams and Miller; and there are two or three of the state experimental stations I am glad to hear from. What I wish to urge is that we shall all of us establish a series of home experiments, and make it a fixed part of our annual efforts in horticulture. These experiments, when they reach fixed results, should be reported on in such a way as to reach the general public.

For many years I have made it a point to cross-breed or specially select both among flowers and vegetables. For ten years I have carried on a series of experiments with Beans, Corn and other garden products. I have raised a Pumpkin that kept with dry storage all summer; but have not held it to be of sufficient value to disseminate. My experiments with Strawberries have never given but two promising sorts, and one of these may at some time prove to be worth general testing. In Raspberries I am testing a strain of very early red seedlings that so far promise to be superior to Turner, Marlboro and other early sorts—certainly far ahead of Hansell, Crimson Beauty and Lost Rubies. I have no Blackberry that I am certain of, but some good ones. Black Raspberries follow their parentage very closely. What I hope for is a seedling Gregg that shall be absolutely hardy. Seedling Grapes have shown some good points, but nothing to warrant their being sold. The Gooseberry is a grand fruit, growing slowly into popularity. I have succeeded in starting, or rather finding, a true cross of native and English that, after five years' test, I believe to be an advance on what we have.

Corn I have crossed quite to my heart's content, and the result is many very good sorts, from very early to very late; but I am not sure that they should be offered to the public. In Beans I have had better success. A white Wax-pod ten inches long and three inches around is big enough. The beans inside in some sorts number nine or ten and are white in color; in others pink or yellow.

Comparative culture opens another admirable field for home experiments, only that it requires far more patience than is often exercised. Very many reports as to the comparative merits of deep or shallow planting, level or hill culture, the merits of seed from the end or from the middle of the ear, of small or large tubers, etc., are vitiated by the variation of seasons.

But whatever results may prove of advantage to the public, these experiments are of immense importance to the farmer or gardener who works at them, and to his family. They lend a charm to rural life that is hardly obtainable in any other way; turning hand-work into head-work, and drudgery into poetry. The effect on children is most admirable. I should by all means allow each child a special part in a special experiment; let him work it out himself. Here he gains the power to investigate and observe, which makes all scientific research and acquisition possible. An experimental plot is better than botany books. Hired men will also be greatly improved by being engaged in comparative culture.

Clinton, N. Y.

E. P. Powell.

Shirley Poppies.

To the Editor of GARDEN AND FOREST:

Sir.—Will you be kind enough to tell me what is a Shirley Poppy and how it differs from other Poppies?

Morristown, N. J.

B.

[These Poppies were produced by selection by the Rev. W. Wilks, of Shirley Vicarage, England. Mr. Wilks found in a corner of his garden a stray lot of the wild scarlet field Poppy (*Papaver Rhæas*), and amongst them he noticed one blossom whose petals were distinctly edged with white, with their bases shading into the black of the stamens. A second plant he found near his home with the same white edging, and having saved the seed, the next year gave him a few blossoms which were more or less edged with white, and some others of a paler shade of red. The seed of the most distinct ones was saved from year to year, and Mr. Wilks is positive that he still finds improvement in the plants. In some of them all the dark tinge has been removed at the base of the petals, and golden stamens and anthers have taken the place of the sombre centre of the flower, and the color of the petals varies from pure scarlet to paper white, including all shades of pink and salmon-pink.

The plants have grown in vigor and robustness of habit as well as in beauty. The strain has become so well established that not more than one per cent. of "rogues" or black-centred flowers are found. A good colored plate of these Poppies was published in *Amateur Gardening* July 5th, 1890.—Ed.]

The Fay Currant.

To the Editor of GARDEN AND FOREST:

Sir.—I observe that Mr. E. P. Powell speaks disparagingly of the Fay Currant in your issue of July 23d. My experience has differed so completely from his that I am led to inquire whether his views are generally accepted. Either the conditions at his place are exceptionally unfavorable for this fruit or the conditions with me are unusually good, for it is by odds the best Currant I have ever tried.

New Haven.

S. V. C.

[So far as our observation goes the Fay Currant is altogether a superior fruit. Many correspondents corroborate this opinion. Dr. Hoskins, for example, writes from Vermont that it is a great success with him and far ahead of the Versailles on rather light soil. The clusters are almost like Delaware Grapes in size, they sell well, and no complaint is ever made of their quality. Mr. S. D. Willard writes from Geneva that his experience with this Currant is most favorable, and he adds that he considers this the prevailing sentiment among horticulturists of western New York.—Ed.]

Recent Publications.

The Trees of North-eastern America. Illustrated from original sketches. By Charles S. Newhall. 8vo, pp. 242.

This work has been prepared for the sole purpose of enabling persons who have no botanical knowledge to identify the native trees of Canada and the northern states east of the Mississippi River, and a few—some twenty or more—of the more common species that have been introduced and naturalized in this region. The characters used are few in number, and mainly those which are most obvious. The leaves of the trees are principally relied upon in the descriptions given, and the classification is based on leaf-forms exclusively. The plan is for the student to take a leaf of his specimen, and follow it down through a few of its plainest characters—that is, whether simple or compound, alternate or opposite, entire, toothed or lobed, and if the latter, whether the lobes are entire or toothed. Having pursued his specimen to this group the student will find the leaves of all the trees of its class rather coarsely figured from what appear to be actual impressions from typical specimens. The figures are accompanied by brief descriptive text, which gives additional data for identification, drawn from the bark, flowers and fruit.

Since the book has an aim so definite it may have been advisable to omit any details that are not absolutely needed for

that single end. For example, there is no need of giving any description of the winter-buds of trees, for the key can only be used with the leaves. No mention of their flowers is made in the case of several trees, and perhaps it is enough to say of the flowers of the Sassafras, "greenish yellow, in clusters, May, June," or of the Yellow Willow, "blossoms, May." But such information is not very specific or satisfying. We may not unreasonably hope, however, that one who has taken the pains to identify a tree by means of this artificial guide will continue his investigations until he learns something of it besides its name. The truth is, however, that very few people comparatively can identify half the trees in our woods or by our roadsides, and this book will render a worthy service by helping all who follow its plain directions to call our familiar trees by their proper names.

Professor N. L. Britton has been followed as the authority on scientific nomenclature.

Report on the Substitution of Metal for Wood in Railroad Ties. By E. E. Russell Tratman. Published by authority of the Secretary of Agriculture, Washington.

This report has just been issued by the Forestry Division of the United States Department of Agriculture as "Bulletin No. 4," and while it has a special interest for railroad managers and engineers, it will be found of value to all intelligent people who give attention to the subject of forestry in general as one of the necessary economies of modern civilization. Mr. Tratman, who made this investigation on the consumption of ties, obtained his information by addressing the managers of various railroads at home and in foreign countries, and they furnished full information in reply to numerous circulars and letters. The report covers some 350 pages, besides many careful illustrations, so that it will be impossible to give anything like a summary of the information given. It is sufficient for the present purpose to say that probably there are now in the world 30,000 miles of railway laid on metal ties, which amounts to nearly sixteen per cent. of the total mileage of the world, exclusive of the United States and Canada. These figures show not only the great importance of the subject considered, but they show also that in other countries this subject has long ago passed the experimental stage in which it still remains in this country.

Of course the use of metal ties is in the interest of forestry and in the interest of the timber resources of the country, but it is also in the interest of the railways, because it reduces the expenses of maintenance and increases the safety of operation. Mr. Tratman concludes, therefore, that the introduction of metal ties will be a benefit to the forests, to the railways and to the public. The indirect value to the country and to our forests of this change to metal ties can only be realized when we consider the large amount of forest-supplies that are used in railway construction. Probably the railways use not less than one-fifth of all the timber consumed in the country. But what is of more importance, the material represented in this consumption is drawn largely from thrifty young growth which is the promise of the future, so that the timber crop is used before it has reached its most profitable age and largest production to the acre. Besides this, the most durable and valuable timbers only are desired, and consequently the forest-areas from which these kinds are culled must deteriorate in quality, the inferior ones being left to dominate and exclude more valuable kinds which are thus placed at a disadvantage by the unintelligent action of man. That this is true is proved from investigation in the forests of Kentucky, where White Oak represents forty per cent. of the natural growth, while after the timber has been culled the new growth contains not more than five per cent. of this valuable railroad timber.

The great bulk of the tie material is now cut from second growth, especially in the eastern states, and young timber that will make only one tie, or at least one tie to the cut, is called for in most specifications. This careless consumption of the best parts of the new growth must injure the future forest; for we draw in this way upon the fund which we should hold in trust and should allow to accumulate for the next generation. We do worse, indeed, because we do all we can to depreciate the value of the investment by injuring its quality.

Many considerations of this sort are brought out in a suggestive introductory note by Mr. Fernow, from which we quote the following:

"It has been shown repeatedly that our annual consumption of wood products at present exceeds double the amount of wood material that can possibly reproduce itself annually on the area covered with wood growth. It is, therefore, of national interest and within the line of work of this Division to call attention to the necessity of husbanding timber supplies,

and to furnish all and any information that may lead to a more economical use of these supplies or a substitution of other material where this is practicable. While such economy is desirable in all directions, it is especially so in regard to tie-timber, since, for this purpose, the promising crop of the future is utilized prematurely—and that of the best quality and of the most valuable timbers. Furthermore, it should be known that for those who furnish these supplies for the railroad companies there is but small, if any, profit in the trade. The ties are in most cases brought to the railroads by holders of small wood-lots, and the price paid is hardly more than fair compensation for labor in making and hauling them, no value being placed upon the material itself.

"It has been suggested that railroads could be induced to substitute metal for wood only when it could be shown that an increase in the price of wooden ties is imminent. But from this report it appears that the price paid for ties in many localities is now even lower than it was formerly, notably in the north-eastern states. Yet it would be a mistake to argue from this, as a general proposition, that more timber is in the country than before, that forest-supplies are in excess of demand, and that prices are going to decrease continuously.

"The law of supply and demand as affecting the price of this commodity is vitiated by other conditions which influence the price. It is the excessive offer compared with the requirements, rather than excess of actual visible supplies available for the long run, that places the purchaser of this commodity in position to dictate the price, the offer coming from many holders of small parcels, who have no knowledge of general market conditions, and hence cannot take advantage of a comparison between actual supplies in view and demand for the present and future in adjusting the price.

"A timber crop, unlike an agricultural crop, is capable of being harvested at various stages of development. Timber fit for ties may be cut at any time, from the twenty-year-old sprout of the coppice to the old growth of the virgin forest, and the offer of the crop in this shape may be excessive at any time without necessarily indicating an over-abundance of forest-supplies in general and for the long run. The accidental simultaneous arrival at an age when the timber is fit for ties of a new growth over a large area may also in a given region make supplies appear plentiful, and, therefore, for a time reduce the price; but this present over-supply and reduction of price must necessarily be at the expense of a future short supply and increase of price. Another reason for an apparent over-supply of tie timber may be found in the opening up of new sources of supply on such roads as are capable of extension, while the old roads, with no new fields to enter, will necessarily experience a constant advance in prices with decreased offers, and will be the first to have recourse to metal on account of cheapness.

"It should also be known that, within limits, a railroad management has it in its power to keep the price low by raising freight rates, so as to make the exportation of tie timber from its territory unprofitable. The condition of the tie market, then, cannot be the only, or even the main, criterion as to when the time for substituting metal has arrived, even from a financial point of view.

"But it is not a consideration of initial cost that makes the substitution of metal ties desirable and profitable. It is superiority of track, permanence of road-bed, safety, reduced cost of maintenance, and hence ultimate saving and economy, that recommend the metal tie, as the experiences in foreign countries have proved.

"A curious lack of accurate calculation is often seen when comparisons are made on the balance-sheet between various systems of construction. If initial cost alone is considered, all financial questions are settled by the amount of cash on hand, but the question with stable corporations is whether temporary saving in initial cost is preferable to greater initial expenditure where it ensures decreased outlay for maintenance and deferred expenditure for renewal.

"From a simple calculation it will appear, for instance, that a road using ties for which it pays fifty cents, and which last eight years—like white Oak in many sections—can afford to pay \$1.20 for a metal tie lasting thirty years (the presumed life of such ties) and be sure of saving at least the amount required for the renewals of the Oak ties during thirty years; or, by doubling the life of the Oak tie to sixteen years by means of preservative processes, we may pay thirty-five cents for such process and still find an advantage on the balance-sheet."

The Bulletin also contains a paper by Mr. Fernow on the consumption of forest-supplies by railroads and practicable economies in their use, to which, as well as to some details of Mr. Tratman's work, we hope to refer in a future issue.

Notes.

The eleven parks in the City of Philadelphia are estimated to contain 2,884½ acres of ground.

General Bidwell has added 700 acres to his orchard in Chico, California, so that it now covers 2,200 acres.

Mr. Carl W. Hartmann, of Sweden, is the botanist of the Lumpholtz Mexican Exploring Expedition, which started from Arizona on August 30th, and hopes to return in the autumn of 1892.

English journals say that the custom of tree-planting by school children on a certain day in each year has been imported from America into Australia, in accordance with the decision of the Minister for Public Instruction. There, as here, the day will be known as Arbor Day.

A garden of Pampas Grass ten acres in extent is one of the objects of interest to tourists who visit Anaheim, California. This year about 40,000 plumes will be harvested, and the yield after the plants become fully established will average 100,000 plumes. These plumes bring about five cents apiece.

As the fragrance, if not the savor, of strawberries is injured by washing, the *Revue Horticole* recommends that, when it is desired to free them from sand, they should be gently bounced in a piece of damp muslin. The sand will remain attached to the muslin and the delicacy of the fruit will not be impaired.

Mr. E. S. Miller, writing from Floral Park, Long Island, in reference to Mr. Orpet's method of propagating Achilleas from underground stolons, says that his way of getting a stock of these plants is to store the old ones in a shed until January, then plant them in a bench and take cuttings from the young wood from that time on until May. Plants struck as late as May, if planted out, make very strong roots and give an abundance of flowers.

The *Garden* says of *Lilium Henryi*: "The species is a new one, and was discovered in western China by Dr. Henry, who sent a few bulbs of it to Kew last year. The habit of the plant is that of *L. lancifolium*, but taller; the flowers are in loose corymbs, specimens showing as many as eight flowers on each stem; they are reflexed as in *L. lancifolium*, three inches across, and colored rich orange-yellow, with a few tiny dots of purple. As a decorative plant this species will take rank with *L. tigrinum* and *L. superbum*."

The *Garden* recently noticed a new Peony as both "curious and beautiful." It is called *Pæonia Wittmanniana*, and "when the leaves first appear their bright, pale, golden green color must strike any grower of plants accustomed only to the deep toned leaves of the better known herbaceous kinds. But the picture is complete when the flower appears, of a beautiful and delicate color that may best be described as strong primrose with a dash of lemon. The texture of the petals is so firm as to remind one of a Magnolia, and the seed-pod is a bold and handsome object."

The *Gardeners' Chronicle* for August 18th described at length American methods of evaporating fruit, prompted by the fact that the subject had been discussed at a recent meeting of the Royal Horticultural Society. It seems that the industry is as yet unknown in England, but it is believed, might profitably be developed there, although the fruit production of the country is on a scale so much smaller than our own. The best way of introducing it, one speaker at the meeting had said, would be for some land-owner to "set up one of these American evaporators, so as to give his tenants and neighbors an opportunity of testing its value."

Under the title of *Variétés Bibliographiques* Monsieur Rolland, a Parisian bookseller, is now publishing an interesting, popular flora, which is to include as many vernacular names for each plant as can be discovered, and also all the stories, superstitions, proverbs and customs relating to the plants and flowers of all parts of the world. As an extreme example of the perplexing number of common names which may be borne by a well known plant a foreign reviewer cites from this book the case of *Clematis vitalba*, for which more than 200 such names are recorded, not, of course, in French alone, but in the different languages included in the scope of the encyclopedia.

Boston journals announce the closing, after a most successful third season, of the seventeen summer play-grounds for little children established by the Massachusetts Emergency

and Hygiene Association. Almost all of them were public school-yards, and although in only one was it possible to form a flower-garden, the open spaces, filled with heaps of sand, supplied by charitable individuals with toys, cut flowers and sea-shells, and superintended by a matron, have given health and happiness to a multitude of indigent children who otherwise could have found recreation only in the gutter. The average attendance for the whole summer was ninety children daily at each of the yards. At some of them the daily total occasionally rose to as many as 200.

In spite of the unfavorable year the horticultural exhibit at the New Jersey State Fair at Waverly last week, and especially the display of apples and pears, was unexpectedly fine, although not as large as usual, while the grapes were fully up to previous exhibits, and potatoes were abundant and superior in size and smoothness. The most tempting of the pears were from cold storage; the Bartlett's, Boussocks and other early varieties being especially attractive. The greater part of the grape display came from Montclair, and finer clusters of Brighton, Cottage, Concord, Worden and Niagara were never seen anywhere. Samples of the new white grape, Colerain, were on exhibition. The clusters and berries were of medium size, but the quality was pronounced excellent by all.

The *Evening Transcript*, of Boston, recently gave, on the authority of the *Westborough Chronotype*, an account of a great Elm-tree which stands in the westerly part of Framingham, Massachusetts. It was transplanted from the woods by one Jonathan Rugg in the year 1774, and set in rich, moist ground to shelter a little house which had been built just seventy years earlier. At one foot from the ground it now measures twenty-eight feet six inches in circumference, while the girth of its largest limb is ten feet three inches. The circumference of its noon-tide shadow is 295 feet, an area, we are told, "that would readily accommodate two thousand people." Under one huge branch stands a two-storied farm-house and a flight of steps ascends the trunk and follows another limb to the place of its forking, where a capacious summer-house has been built. The giant tree is still healthy and vigorous.

French journals lament that unfavorable weather has almost altogether deprived the country of fruit this year. A disastrous amount of rain has so afflicted the central, northern, western and south-western districts that the markets have been almost bare of fruit except such as had come from the south. One correspondent, writing from the Department of the Seine-et-Marne, says: "We have had neither cherries nor apricots nor plums; apples have been greatly injured by hail; pears have suffered less; but our grapes will not ripen." And another, writing from Brittany, says that there the pears are all spoiled, apples are lacking in many localities, and almost all the plums had perished; that peaches are everywhere non-existent; that gooseberries and raspberries had been relatively scanty, and that, although strawberries had been quite plentiful, they "had only the form of the fruit with the taste of water." Meanwhile, complaints of excessive drought have been coming in from the south, where, we are told, even in carefully watered gardens, the trees and shrubs had faded and withered. Near the coast the moist sea-breezes "assure the abundance of the grape crop," but further north grape-growers are reported to be in despair over the persistent dryness.

We are accustomed to hearing the Ailanthus condemned as an avenue-tree, because of the irritating effect of its pollen on the bronchial tubes and its consequent offense to those who are afflicted with "hay fever." But, according to one of the editors of the *Revue Horticole*, the Plane-tree is equally undesirable, by reason of the fine hairs which cover the lower surfaces of the leaves, the buds, and even the young fruits. "These hairs, being extremely light, spread through the air, and, introducing themselves into the respiratory tubes, irritate the mucous membrane to such an extent that workmen in nurseries are obliged to cease their labor during the heat of the day. These facts are so well known, that when the grafting of Planes or even the clearing of the soil where they grow is in question, care is taken to have the work stopped when the sun rises and the dew disappears, because then the hairs detach themselves and cause an irritating cough, which sometimes even produces hemorrhage. The danger is said to be much smaller in streets than in nurseries, for the trees are then lifted well above the ground and the wind carries off most of the injurious hairs; nevertheless, the writer pronounces it a genuine danger even under these conditions, and calls to it the attention of those who superintend the planting of Parisian streets."

The Tupelo Tree.

THE forests of eastern America contain few trees more interesting to the botanist or of greater ornamental value than the Tupelo, Pepperidge, Sour Gum or Water Gum, as one of the American representatives of the small genus *Nyssa* is popularly called in different parts of the country. This genus was so named by Linnæus for a water nymph, because the species known to him, inhabitants of our far southern states, grow usually in shallow ponds or deep swamps overflowed for a considerable part of each year. Its nearest American relatives are the Cornels, from which *Nyssa* differs principally in its five instead of four-parted flowers, which are rarely perfect, but produce their male and female organs separately, while the flowers of the Cornels are perfect, and, in its alternate leaves, the leaves of our Cornels being opposite except in the case of a single species.

The distribution of the genus is exceptional and interesting. Three species, or four, according to the opinion of some excellent observers, inhabit different parts of eastern North America from Maine to Texas. One species, a tree of some size, occurs at considerable elevations on the Sikim Himalaya, and one or two little known species are found on the mountains of Java. The genus has no representative, strange to say, in the flora of China or Japan, where so many of the types of eastern America occur; and paleontologists have not yet brought to light any indication that the ancestors of existing species inhabited a larger part of the earth's surface than these species do at present.

This is not the place, and it is not our intention, to discuss at this time the limits of the different American species, which have puzzled botanists ever since they have known them, the confusion beginning with Linnæus himself, who included two very distinct species under his original description. It is our purpose merely to call attention to one of the species still little known or appreciated by planters as an ornamental tree. This is the *Nyssa*, which is generally distributed through all the eastern portions of the United States south of the southern part of the state of Maine and central Michigan. *Nyssa aquatica* appears to be the correct botanical name for this tree,

although it is only in the extreme south that it grows in water. Near the coast of the northern states it always grows by the borders of swamps in low, moist ground; and in the interior, especially on the lower slopes of the high Alleghany Mountains, where it attains its greatest size, it is found at considerable distances from the water-courses associated with the Oaks, Magnolias, Hemlocks, Hickories and Ashes which form the principal part of the forest-growth. Here the Tupelo grows sometimes to a height of considerably more than a hundred feet, with a tall, stout trunk three or four feet in diameter, and short slender branches, contracted in their development by its neighbors in the forest. Near the coast it is always a much smaller tree, especially in the southern states, and it is rare to find it more than fifty feet high except in the mountain forests or in those of the lower Ohio valley—a region of exceptional and extraordinary tree-growth.

The habit of this tree as we see it near the coast is very different from that which it assumes when growing in the dense forest, for, as it grows near the coast in low, wet land, which produces generally few trees, the individuals have sufficient room for the development of their branches, which are long and nearly horizontal, producing a flat, often umbrella-shaped, top. This is the familiar form in which the Tupelo is seen in the neighborhood of this city, either along the shores of Long Island Sound, where it abounds, or the New Jersey coast.

The leaves vary much in size and somewhat in outline on trees in different parts of the country, the largest and broadest being produced on the Alleghany Mountains, and the smallest in the Florida Pine-barrens. The flowers in the different forms vary, however, very little. The staminate flowers are produced in dense clusters, while the female flowers are borne two to fourteen together at the summit of an elongated peduncle. The blue-black fruit, of which rarely more than two are developed from a cluster of flowers, varies somewhat in shape, and very considerably in size, in different parts of the country, as do the seeds, which have been depended on to divide the species. But the botanist, with a large series of specimens gathered from trees growing under the various climatic conditions to which this species is subjected, finds it a difficult task to distinguish characters which can be depended on to establish varieties even which do not pass imperceptibly one into another.

The Tupelo was introduced into England in 1808 by John Lyon, an English plant-collector who traveled widely in North America early in the century. It was doubtless sent earlier to France, as it is hardly possible that Michaux could have failed to introduce such a distinct and beautiful tree into the plantations of his native land. Whether this is true or not it is certain that no American tree is now more rarely seen in Europe, and a really fine specimen outside of America is not easily recalled. This is due, perhaps, to the difficulty which is always experienced in transplanting this tree after it has been allowed to remain undisturbed for any length of time or after it has attained to any considerable size. The roots are remarkably stout and long, with few rootlets, so that the trees are never easy to move unless they have been grown in the nursery and specially prepared for transplanting. It is easily raised from seed, however, the seedlings are easily transplanted, and if they are set while still young where the trees are to grow permanently, no difficulty will be experienced with them. Even large plants dug up in the swamps can be successfully moved if extraordinary care is taken in the operation, but for the ordinary cultivator it is best to depend on small, nursery-grown plants when they can be obtained.

The Tupelo should be more often seen in ornamental plantations than it is at present. The habit of this tree when allowed sufficient room in which to grow is striking and interesting and quite unlike that assumed by any other of our hardy trees. The foliage is abundant and lustrous, and in the autumn it assumes a brilliancy and splendor of coloring

unrivaled by that of our other trees. It is one of those trees which always attract attention—in the winter by its peculiar habit, in summer by the beauty of its foliage and in autumn by its coloring.

The wood of this tree is nearly white and very light, but with such an intricately contorted grain that it can be split only with the greatest difficulty. It is valuable, therefore, and now considerably used for the hubs of light wheels and for rollers in glass factories, for ox-yokes and similar purposes.

The value of the Tupelo as an ornamental tree is shown in our illustration on page 491 representing a group of these trees growing naturally near a small pond in the town of West Medford, Massachusetts, and made from one of the excellent tree portraits for which we are indebted to Mr. Henry Brooks.

Nyssa aquatica is a small-fruited species, the stone marked by broad, rounded ridges; the fruit of the two other American species is very much larger, the stones being marked with prominent acute or winged margins. The first of these two species is the *Nyssa uniflora* of botanists, so called because the fertile flowers are solitary. This is a large tree, usually known as the Cotton Gum or Big Tupelo, a hundred feet or more high, and an inhabitant of deep river-swamps, where it grows in immense quantities, generally with the Sweet Gum, from southern Virginia and southern Illinois and Indiana to Florida and Texas. It has ample, usually angular-dentate leaves and peduncled fruit half an inch long, known in the country where it grows as wild olives. It is one of the largest, handsomest and most abundant of the river-swamp trees of the southern states. According to Aiton, it was introduced into England as early as 1735 by the indefatigable Peter Collinson, who no doubt received it from his constant correspondent, John Bartram; it was probably soon lost from gardens, and it is extremely doubtful if it is now anywhere known in a living state outside its native swamps.

The other American species of the genus is a smaller tree than either of the others and much more restricted in its range. It is the so-called Ogeeche Lime, the *Nyssa Ogeche* of botanists, of the coast region of South Carolina and Georgia, and of a few isolated stations of northern and western Florida. It is a shrubby tree, with staminate flowers in large clusters, the fertile solitary and usually perfect. These are followed by olive-shaped scarlet fruit nearly an inch long, and very acid even when fully ripe. It is collected in considerable quantities, being much esteemed when preserved with sugar for its sub-acid flavor. It is known as wild limes or Ogeeche limes. It is doubtful if this tree, although known to Bartram, Marshall, Walter and the early American botanists, has ever been cultivated, although it might well be grown for its fruit in regions where the Orange flourishes.

DURING the discussion on landscape-gardening at the Boston Convention of Florists Mr. C. B. Whitnall, of Milwaukee, in the course of a well constructed argument to justify the use of a natural combination of simple elements in park planting as against the more highly-ornate style, which also had advocates, quoted the following sentence from Mr. McMillan's now famous essay: "The lights and shadows of a painting are carefully studied, and whatever is appreciated in the copy is surely of greater value in the original." Mr. Whitnall went on to inquire if any one ever heard of a noted artist who spent time in copying ribbon lines or carpet patterns or any other of the formal garden designs which may be classified under the general head of decorative planting. Of course, every one must admit that the genuine artist would prefer some nook in the wild-wood or some other piece of unadorned nature as a subject; but, after all, this hardly proves that so-called decorative gardening is altogether to be rejected. It only demonstrates in another way the truth of what we have before stated, and what is no doubt the belief of Mr. Whit-

nall himself, that there are two distinct kinds of gardening. It does not follow that a piece of embroidery is not beautiful and useful in its proper function because an artist does not choose to put it on canvas, nor does it follow that a formal arrangement of plants may not have a legitimate use in certain places because it is not a fit subject for the brush. A true artist must express some sentiment. It is the inner meaning of his subject which he aims to interpret; but an arrangement of plants and flowers which is meant to be strictly ornamental addresses itself to the æsthetic faculty alone, and although it may give great delight on account of its perfect form and brilliant color its beauty is evanescent and superficial. Decorative planting of this sort is essentially transient. The arrangement of the beds may be altered a dozen times during the year, and they are sure to be changed with each season. It can have none of the associations which cluster around a work which has a permanent and continuous life beneath an ever-changing outward form. On the other hand, a natural landscape may have the beauty which an artist always wishes to reproduce, but it may have in addition a profounder meaning which excites the imagination and moves the feelings. All this means that landscape-gardening which deals with the permanent features of scenery, with the sky line and the distance and the shadowy mystery of wood borders, will always furnish subjects for the brush of the artist, while merely decorative gardening, which is concerned with the temporary adornment of smaller spaces, furnishes no such subject. In other words, it offers additional evidence that there are two kinds of garden art essentially distinct in purpose and in effect. There is no necessary conflict between the two styles of planting, but it is plain that each should be restricted to its legitimate field. Any attempt to combine the two by unskilled hands is likely to produce an incongruity in which the best effect of each will be more than neutralized by the other.

Shrubs which Endure Drought.

BARBERRIES.—Some of the Asiatic Barberries have stood the heat and drought in a surprising way. Of these *B. Amurensis* stands well at the head for rapidity of growth, health of foliage and for the very heavy crop of handsome fruit. Several other species are also clean and healthy and loaded with varied and handsome fruit, under conditions which have favored the Cluster Cup Fungus and stunted growth on the common species from west Europe. Among the perfect ones I might name *B. esculenta*, *B. macrocaulea*, *B. carriacea*, *B. Fisheri*, *B. macrophylla*, *B. cratagina*. Our observations favor the belief that in our climate a number of so-called species are free from the Cluster Cup Fungus.

RUSSIAN PRIVET.—While classed as varieties of *Ligustrum vulgare*, the Privets from central Russia are quite unlike the common forms from west Europe, which are tender here. The leaves are broader, darker green, and in all respects more attractive; the plants are absolutely hardy, the flower-racemes are larger, pure white and fragrant, and the bunches of berries are larger, as are the individual berries. When in blossom the flowers were much worn by the ladies on the college grounds and prized for use as cut flowers in vases.

TAMARIX AMURENSIS.—Here the common Tamarix is frozen down during our mildest winter, while that from the Amur is perfectly hardy. It is a dry climate plant, and will grow on the driest embankment in perfect health where nearly all other shrubs would perish. It is now (September 18th) in flower for the third time this season.

CLIMBING HONEYSUCKLE.—What we have from Russia as *Lonicera Germanica* and *L. media* are models of health and vigor, with a grand show of brilliant scarlet berries in clusters at the points of growth. *L. confusa*, as we have it from north-east Germany, appears to be identical with *L. Halleana* from China, but it is a hardier plant and a more profuse bloomer.

BUSH HONEYSUCKLES.—*Lonicera splendens*, from seeds sent us by Professor Sargent, endures drought better, has better foliage and habit, and has a far more abundant crop of handsome fruit than the common *L. Tartarica*, *L. Zyloteum*, *L. Ruprechtiana*, *L. Alberti*, and a half dozen named varieties from

France and Germany of the Splendens type are superior in every respect to the old varieties, and are now loaded with handsome fruit, shown amid clean, handsome foliage.

SALIX ROSMARINIFOLIA.—As an object lesson the attention of the junior class in horticulture was to-day directed to the plants of *Salix rosmarinifolia* from Ellwanger & Barry, and to the variety of the species from Voronesh, in central Russia. Since July there has not been a leaf on the west European variety, while at this late date the Russian form is clothed with perfect dark green, Fern-like foliage, and is an object of beauty. At any season and in any part of the country the Rosemary-leaved Willow from the East will be prized as a lawn shrub.

ROSES.—The varieties of *Rosa rugosa* from China, central Asia and Russia have not flagged a leaf or made less apparent growth than usual during the dry period.

SPIRÆAS.—Of the hardy varieties and species the most perfect and vigorous have been *S. triloba*, *S. Van Houttei*, *S. callosa alba* and *S. rubra* from Russia, *S. hypericifolia* and *S. Nobleana*.

CARAGANAS.—The most northern species, such as *C. arborescens*, have not endured the heat and drought without partial or complete loss of foliage. But some of the shrub varieties from the eastern steppes have stood remarkably well and flowered profusely. Of these *C. fruticosa*, *C. fruticosa variegata*, *C. macrophylla*, *C. mollis glabra* and *C. Redowsky* stand well at the head.

This list only includes a few trees and shrubs studied as object lessons by the junior class yesterday and to-day.

J. L. Budd.

Judging the Quality of Apples.

THE *Maine Farmer* reports Pomologist Van Deman, of the United States Department of Agriculture, as saying in his address to the fruit-growers at the state fair in Lewiston: "I hear that you have taken to testing the Russian apples, which are very poor in quality"; and I wish to enter a protest against the hasty and inconsiderate way in which whole classes of fruit are condemned together. It cannot be justly said of the apples of any country that they are "very poor."

English apples are looked upon by Americans as inferior to their own varieties; and it is even claimed that the best English apples—the Ribston and Blenheim Pippins—are better grown on this side of the Atlantic. But the English, while admitting the brighter color of our apples, deny that the quality is better than in those produced by their own skillful fruit-growers.

When we speak of the quality of apples, the uses to which they are put must be considered. Downing says of the Talman Sweet: "In quality this fruit is scarcely second-rate, but it is a very popular and profitable sort." All over the country Ben Davis meets with criticism as to its quality, yet it is undoubtedly the leading commercial apple of the United States, and Downing classes it as "good to very good." Among Russian apples, Alexander, Red Astrachan and Oldenburgh are rated high upon the American Pomological Society's select list of 369 varieties. This high rating is not accorded to any of these five sorts for dessert quality; yet their value as commercial apples is indisputable, and they are as extensively planted (in some sections, at least) as any varieties on the list. This shows that high dessert quality is not and ought not to be the only standard by which apples are rated "good" or "poor."

Surely it is no more right to condemn the Russian apples as being "very poor" because some of the largest and best known among them belong to the class of culinary apples, than it would be to call all American varieties "very poor" because some of the leading and best known sorts, such as those named above, or others that might be added, are not dessert fruit. Much the larger part of the apples grown in this and other countries is devoted to culinary use. This seems to be forgotten by a large number of writers on fruit, but surely it ought not to be.

In regard to more recently introduced Russian apples it must be said, and borne in mind, that very few of them have had that wide and general testing, without which all pronounced opinion in regard to quality must be looked upon as a "snap judgment." A public official, above all, should beware of anything like the expression of a hasty and immature opinion on subjects of importance specially committed to his charge.

Of the 250 named varieties of Russian Apples that have been brought into this country within the last twenty years, I know no man who can say that he has ever had an opportunity of fairly testing as many as fifty. My own list covers but forty-two varieties, on which I have had more or less fruit. I am

in my sixty-third year, and have been familiar with the apples of New England, the Ohio Valley, the St. Lawrence and Champlain Valleys, and of New York, from my youth; yet I feel no hesitation in saying that the Russian Apples in my orchard are not inferior in size, beauty, productiveness and vigor to the native varieties of any of these sections. They have, indeed, formed the finest and most attractive part of exhibits where they have competed with our native apples, or with the best known apples of western Europe that are grown in America.

As to the quality of these apples as a class, there are but two, possibly three, of mine that I would rate as very poor—or, to be more precise, as poor as the Ben Davis, when grown in New England. These are Green Crimean, the Spreading Pipka and the Yellow Arcadian. In the class of useful culinary Apples the Russian list is rich, and many of these are fully equal to any American or west European apples that I am acquainted with. We have no better market apples of this class for good flavor, easy cooking, salableness or productiveness than the best Russians, of which Red Astrachan, Oldenburgh and Alexander are well known types.

Of strictly dessert apples I have not yet found among the Russians many of the very highest type equal to Garden Royal, Hunt Russet, Grimes' Golden or Peck's Pleasant. But in a class just below these there is a considerable list, increasing rapidly now as the later importations come into bearing. I class as "very good" dessert apples the Yellow Transparent, Switzer, Longfield, Golden White, Autumn Streaked, Zolotoreff, Titus, Popoff and Prolific Sweeting, and these are not only very good, but they are also large, productive and attractive—some of them strikingly beautiful.

The strongest indictment against the Russian Apples, so far, has been the lack of long keepers among them. The earlier importations had hardly any of these, and we are but just beginning to find them among those now coming into bearing of the more recent ones. The fruit-growers of the "cold north" may rest assured that there are good keeping apples among them. This is certain, and also that they are of good to very good quality; but time is required to definitely place them. Though many of us who are trying them have found that the few first fruits of these varieties will keep as well at least as many in the accepted lists of American winter apples, we must have them in quantity, so that they can be handled not as single specimens, but by the barrel and car-load, before their exact status can be assigned them.

I feel sure that when the Russian apples are fairly judged they will make their way easily. No fruit can receive its proper place from a test of specimens sent by mail and cut on arrival, as I suppose has been the case with Mr. Van Deman. There is a time when any fruit is at its best, and eaten too soon or too late it is not possible to rightly know it. Some varieties have a short season as dessert fruit, and this is true not only of summer and fall apples, but of the longer keepers. Jewett's Fine Red, for instance, has a season of less than a month when it is really fine; and all fruit-growers can name other sorts of which the same may be said. There is also a vast difference in the quality of the same variety, according to how it is grown and handled. Some choice sorts never show their merits in the hands of careless persons. The Roxbury Russet is hardly "good" at any time during its long period when undersized or grown on unsuitable soil. But I have eaten these great Russets in May and June that were grown on the red iron soil of some of the Maine hills, when it was a full match for Mr. Van Deman's favorite, Grimes' Golden. It may thus be pronounced "very good" or "very poor," according to circumstances, and the same is true of many of the condemned Russians.

Effect of Forest-Management on Orchards.

MR. FERNOW'S treatment of this subject from the point of view of an entomologist (see p. 462) suggests a paragraph on the relations between the wood-lot and the orchard from the botanical side of the question. The intimate relationship between the Cedar and the Apple-tree was illustrated during the present summer. There were complaints of a serious rust in a large Apple-orchard near Titusville, Mercer County, New Jersey, and in July I found the orchard, which occupies a hill-side, so conspicuously colored by the rust that it was the subject of remark by passengers upon the railroad trains. Not all the trees were equally attacked. The variety known as the Nero was the worst, while some other sorts at that time were nearly free from the rust. In several trees there were two or more kinds of fruit, and one might be rusted badly and the other nearly free.

The orchard is bordered upon two sides by woods containing many Red Cedars. It was evident that the "Neros" were the most rusted upon the side of the orchard next to the Cedar-trees. Two months later the leaves were nearly all off of the "Nero" trees, and while the trees had set full there was no fruit. The other sorts in the orchard had also suffered badly from the rust, but it was later in developing upon them.

Fig. 60. Oviparous Female.

illustration of the intimate relationship in one particular of the forest and the orchard.

The mismanagement in this case consists in permitting the Cedar-trees to stand hard by the orchard, as living propagating-beds of a Fungus which in one of its forms may be of serious injury to the Apple-orchard.

The relation of the Black Knot of the wild Cherry-trees to the cultivated sorts is an instance similar to that of the Apple and Cedar, with the difference that the Fungus runs its whole course upon the same tree, and the wild Cherries simply furnish a constant supply of spores to infest any cultivated Cherry-tree that may be planted near by. The knots appear only when spores have come from some previously infested branch. It is a piece of folly to attempt the growing of Cherries in close proximity to wild plants that are full of knots. What has been said of the Cherries applies equally to the Plums, for these being closely related to the Cherries are attacked by the same knot-producing Fungus. If we are to have clean and healthy Cherry and Plum-trees in our orchards we must go through the wood-lot with the axe in search for all the wild sorts that bear the Black Knot.

The same close relationship exists between the wild Black-berry and Raspberry and those under culture. The rust of the one will spread to the other, and probably the same is true of the Anthracnose that has been so destructive to the cultivated Raspberry during the past year.

Byron D. Halsted.

The White Pine Louse.

THIS insect was first described by Dr. Asa Fitch, in one of his reports on the insects of New York, as *Lachnus Strobi*. Colonies of the plant-lice are said to live upon the ends of the branches of White Pine, puncturing the twigs and extracting the sap, and causing the bark of infested trees to have a peculiar black appearance. Mention is also made of the

Fig. 61. Winged Male.

fact that numbers of ants occur in company with the lice, "traveling up and down the trees which they inhabit."

Very little has since been written concerning this insect. It appears to be a widely distributed species, and from its winter habit it is evident that it is liable to be introduced everywhere with Pine-trees from nurseries. In central Ohio it occasionally becomes sufficiently numerous to seriously injure ornamental Pines. One tree on the University campus here is now almost dead because of its attack.

Like most plant-lice, this species reproduces viviparously during the summer, but on the approach of cold weather the sexed individuals are produced. During October these are usually the only forms present, the oviparous females being congregated in great numbers upon the bark of the smaller branches, with their heads nearly always directed toward the trunk of the tree. When disturbed they move about rapidly, usually attempting to conceal themselves on the other side of the branch. At such times they also have a curious habit of waving their long hind-legs in the air, probably for the purpose of frightening away enemies.

The oviparous female is represented, magnified, at Fig. 60. It is about .1576 of an inch long, shining black, more or less tinged with brown, and ornamented with spots and stripes of white, as represented in the illustration. The winged male is also shown magnified at Fig. 61. The body is .1788 of an inch long, and the wings expand about .2758 of an inch. The insect is blackish, with a slight glaucous bloom, and a white longitudinal line along the middle of the back.

The eggs are deposited during October and November on the leaflets in rows, as represented in Fig. 62 (a). Each egg is .0788 of an inch long, elongato-oval, brownish when first laid, but becoming black in a short time.

Fig. 62.—a, EGGS ON LEAF; b, EGG, MAGNIFIED.

One of the best remedies for this pest is kerosene emulsion. There are also many natural enemies that keep it in check.

Clarence M. Weed.

New or Little Known Plants.

Leucophyllum Texanum.

LEUCOPHYLLUM is a small Mexican genus representing a tribe in the great family of the Figworts or *Scrophulariaceae*. Its near relatives botanically in our flora are the Mulleins, the Figworts, the Snapdragons, and other familiar plants of the field and garden. The Leucophyllums, of which three or four species are distinguished, are low, intricately branched shrubs, inhabitants of the desert, and distinguished by the silvery white wool which covers the lower surface of the leaves, and by the large, showy, axillary flowers. Two species reach the southern borders of Texas, *L. Texanum* and *L. minus*. The former, of which a figure appears on page 489, is a loose-growing shrub of straggling habit, attaining, under favorable conditions, a height of eight or ten feet, although it is rare to find it in Texas more than half that size. There is no shrub of the desert portions of the valley of the lower Rio Grande more generally distributed, and certainly there is not one of them which more delights the traveler in the early spring months, when the large, violet-purple flowers of this plant heighten the effect of its brilliant silvery foliage.

The leaves are half an inch to an inch long, obovate and almost sessile, pale gray on the lower surface like the shoots of the year and silvery white below. The flowers

are an inch or more across when expanded, with lanceolate-oblong calyx-lobes, a campanulate corolla slightly villose on the inner surface, with five rounded, nearly equal lobes, four included stamens and an emarginate stigma. The fruit is a two-valved capsule.

*Leucophyllum Texanum** was discovered many years ago

taken in hand, however, a few years ago by Mr. P. J. Berckmans, of Augusta, Georgia, in whose garden it flowered during the past summer for the first time probably in cultivation; and it is from a specimen of one of the cultivated plants that Mr. Faxon has made the drawing which is reproduced in our illustration.

Fig. 63.—*Leucophyllum Texanum*.—See page 488.

by the Swiss botanist, Berlandier, a pupil and protégé of the elder De Candolle, who early emigrated to Matamoras and first explored the flora of the valley of the lower Rio Grande and of the Mexican Sierra Madre. In spite of its beauty it long escaped the attention of cultivators. It was

*I.—Bentham in De Candolle's "Prod.," x., 344.—Gray, "Bot. Mex. Bound. Surv.," 115; "Syn. Fl. N. Am.," ii., 250.

Leucophyllum Texanum, although, according to Mr. Berckmans, it is difficult to propagate, is so ornamental in foliage and in flower that it will certainly become a popular garden plant wherever the climate is sufficiently dry and warm for its successful cultivation. A more interesting American plant has not flowered for the first time this year in any garden.

Cultural Department.

Vineyard Notes.

ONE who has a vineyard is always sure of a surprise. After setting it down very positively that a certain variety has certain specific qualities, he is mortified to find that the next year reverses all his experience.

So it is that in 1890 I am quite confounded about several Grapes. Ulster and Vergennes are to be marked up, while Lindley goes down once more. Lady is where it was, the earliest and best; but so poor a bearer as to be useless. Hayes is up another notch, and behaves regularly so well that it seems to deserve the foremost place among delicious, prolific and handsome early white Grapes. Then Diamond, a little later, is first-rate. No disease touches it except anthracnose on the vine. The bunches and berries are both large and fine. It is handsome, prolific, healthy and an acquisition not easily overpraised. Niagara rotted last year, but this year is grand enough to make up. It is not so good a Grape as Diamond or as Hayes, but larger in bunch, and will outbear any Grape unless it be Worden. Empire State is a failure here in all ways. It is not of high quality nor always prolific, and shrivels on the stem after picking. Duchess is fine, but this year failed to fertilize well. Prentiss is good for nothing. Jessica is half seeds, a small bunch, a tepid flavor. Golden Gem is a spicy little affair, but very small. It grows about like Jessica, and a vine grower would get rich on one as soon as on the other. Purity is a really fine, very early Grape, ripening just after Lady. It is handsome and healthy, with a large berry and large bunch. Grein's No. 7 is worthless, a very small berry, without quality and half seeds. Grein's Golden is the handsomest of white Grapes, but has an odd acid flavor. Pocklington is a late white Grape that is admirable when fully ripe. It needs a favorable season. I should place it after Hayes, Diamond and Niagara. But when it ripens it will make with them a splendid quartette. Martha, when thinned in bunches, is a really fine white Grape for everybody. Eldorado is an ideal in quality and bears fairly well, but the bunches are imperfect. The general reports from it are of the same character. This completes the list of white Grapes of prominence except those grown mostly for wine.

Of red Grapes, Brighton fairly heads the list. It is a marvel in quality, a seedling of Iona, which it resembles, very early, ripening, however, all along through September. Enormously prolific, if grown with other Grapes; but if grown alone, it often fails to fertilize its flowers. Gaertner is another red of superior quality. It is noble in bunch, berry and quality, ripening with Hayes just after the earliest Grapes. Salem is better known, but is not quite so good as Gaertner. Lindley and Massasoit are much alike; they often fail to fertilize under the best conditions. In quality they are of the highest, but are too doubtful to be generally planted. Massasoit is the most subject to black rot of all Grapes in my collection. Ulster is a really good Grape, but was sent out so overforced that the spindling vines damaged its reputation. Vergennes is doing better with me each year. Rogers' 30, a pale red, has been one of my favorites; but for two years it has failed to fertilize. Goethe, another Rogers of the pale red sort, is superb in quality if you can ripen it. Iona is perhaps best of all Grapes, but is seldom seen in the vineyard, because too tender. Goethe and Iona are best treated as pets on the south side of the house. Poughkeepsie Red is a solid bunched Delaware; it may be valuable in some localities. Agawam has come to me from reliable growers in two forms, and I think there really are two Agawams settled on the market. The earlier one is very fine, ripening with Gaertner; the late one is neither prolific nor good. Jefferson is food for the gods, but I cannot ripen it well in this section. Woodruff Red is a second-quality Grape, but perfectly healthy, with splendid foliage, a rampant grower, and the bunches are of compact, medium size. It is a good runaway Grape, where people do little in the way of culture and are not over nice about quality. Diana should be grown for a late red, ripening about with Woodruff. The bunch is very fine, and the vine both hardy and prolific. Walter completes my list of noticeable red Grapes, and is very fine. It looks like a large Delaware bunch, and bears well and is hardy.

Of the black Grapes, Worden, by all odds, heads the list. It is a Concord in all a Concord's good qualities, and leaves out the bad ones. It is fit to eat as soon as colored, two weeks ahead of Concord. Herbert, in my judgment, is the best later black. Barry and Wilder are fine. Moore's Early has once or twice given me a good crop, and it is so early as to be very valuable when you get fruit; but it is tricky. August Giant is worthy of mention as a large grape of good quality, a little later than Concord, and an extraordinary grower.

Our list, except for experiment, may be greatly shortened. Take Hayes, Diamond, Niagara for white; Brighton, Gaertner and Delaware for red; Worden and Herbert for black, and then pet Iona and Goethe, and you have ten as good as you need.

There should be a much more liberal planting of Grapes for home use. When only one vine is planted, take Worden. For two, Worden and Niagara.

Clinton, N. Y.

E. P. Powell.

Timely Hints for Fruit Growers.

THOSE persons who are making preparations to plant new fruit gardens or to add to their old ones during the present autumn should remember that there are many old trees which have lost their vigor, and bear reduced crops, with poorer quality. In some cases a more satisfactory result may be obtained by restoring the old trees than by planting new ones, giving immediate and larger crops than the young trees, which require years to come into bearing. There are two means by which old trees may be restored—pruning and enriching cultivation. The pruning must be moderate and judiciously applied, taking out all dead limbs if present, and giving mellow cultivation in connection with manuring, either broadcast over the orchard or in broad circles around the trees as far from the trunk as the height of the tree. Heavy top-dressing with manure will accomplish much even on grass land without cultivation. We have known this treatment, applied to trees which had many dead twigs and branches and had nearly ceased bearing, to restore them to strong and healthy growth, affording crops of fruit, the specimens as large and fine as those growing on young trees. An essential requisite for such success is in undertaking no more than can be accomplished, and not spreading the enriching process over much ground.

Apple-trees require less frequent renewal than some other fruit-trees, and under the best management will grow and bear well in the more eastern states for fifty years or more, and half that period at the west; sometimes they have lived to seventy or eighty years. Those which stand in the corners of cultivated gardens, where they receive all the requirements for good culture, generally outlive all others.

A moderate amount of pruning, especially of dead limbs, may be performed in autumn, but if the trees receive much cutting it makes them more tender for the time, and the work should be left till early spring.

It is often desired to increase and extend old orchards which give fruit for family use, and when this is the case a careful selection of varieties is better than a larger indiscriminate number. A succession, which will afford fruit for the table or for cooking during every day in the year, will be especially valuable. As the earliest fruit continues for a short time only, fewer trees will be required; autumn varieties keep longer, and larger quantities will be needed; while long-keeping winter apples, to supply a period of as many months as the early sorts do for summer, should constitute two-thirds or three-fourths of the whole planting.

The same care must be given in providing a well-prepared piece of ground for other fruits. With Peach-trees clean and mellow cultivation is more important than with most other fruits; while Cherries will endure short grass and moderate fertility. Plums generally do better with rich, cultivated land, and are stunted in grass or in a hard soil and thick crust. A top-dressing with manure on soils where the leaf-blight prevails often prolongs the season of growth; and vigor imparted to Peach-trees early in the season is the best remedy for the curl of the leaf.

As a summary, therefore, or general directions, there are two points to be well borne in mind in planting fruit-trees, whether in autumn or in spring; namely, well prepared, enriched and well cultivated land; and then only as many trees set out as can receive the best attention—selecting those which will afford as nearly a regular succession as practical. Productive varieties will be more profitable in supplying the family than thin and uncertain bearers; and it will cost no more to set such as are of delicious quality than those that are unfit to eat. And the importance of good cultivation must be constantly and at all times remembered, and the great superiority borne in mind of such fruit as comes from well treated trees. A single tree, under the best treatment, may give handsome, juicy, delicious specimens, fit to grace the finest table, and gratify the most refined appetite, and be incomparably better than the product of a dozen neglected trees with their scabby, distorted, insect-bitten specimens and poor flavor. Plant moderately, therefore, and give the most thorough culture, as the cheapest way to obtain full and satisfactory returns.

—The Country Gentleman.

The Tupelo Tree (*Nyssa aquatica*) in Eastern Massachusetts.—See page 485.

Hybrid Violas.

A CORRESPONDENT of the *Gardeners' Chronicle* makes the following notes on these Tufted Pansies, as they have been appropriately called :

These plants are rapidly growing in favor, and for bedding purposes they are invaluable. I know of nothing that can surpass the effect they produce when judiciously planted, and few flowers are more adaptable. Large two or three-year-old clumps of Violas are the most beautiful objects one can have in a garden in May and June, a period when the flowers are most numerous produced.

Amongst sterling new kinds put in commerce this year may be mentioned Duchess of Fife (Baxter), light primrose, distinctly edged with blue, a strong grower and good habit, an improvement on Goldfinch; this novelty will be a leading flower in future years. Ada Adair (Baxter), clear shining rose, dark centre; very pleasing flower, and one of the best twelve. Delicata (Baxter), soft, rosy lilac; quite a new shade, a taking flower, and a very free grower. Crimson King (Baxter), rich crimson, primrose eye, white brows; a finely formed flower, and the best of this shade.

In the list of good but somewhat older kinds, we may name John Burns, rich dark velvet purple, heavily marbled with light peach, white brow, clear eye. Countess of Hopetoun, pure white, compact habit, free bloomer. Holyrood, dark blue, compact habit, extra fine. York and Lancaster, dark purple, beautifully striped with white, shaded with rose; very pretty. The Mearns, rich plum, upper petals edged with white; very attractive. Evelyn, dark blue, shaded white; very fine. Mrs. Baxter, dark purple, with pure white top petals, extra large flower, free habit; best of its class. Sovereign, golden-yellow, compact, immense bloomer. Picturata, mauve; very fine. Neptune, purple, with light back petals. Royalty, bright yellow; first-rate. Columbine, white, margined with rosy-lilac; extra fine. Lucy Ashton, little centre, edged all round with a broad band of rosy pink, after the style of Columbine, but retains its color much better in hot weather; a vigorous grower. Gipsy Queen, very light lilac, heavily streaked with violet; a novel and pretty flower. Hugh Ainslie, top petals bluish mauve, shading to white, under petals rich indigo-purple; clear yellow eye, surmounted with white brows; a large, showy flower and a free bloomer. Mrs. H. Bellamy, upper petals pale lavender, under petals deep solid purple; fine clear yellow eye, with white brows; large, circular and smooth as a show Pansy; a free grower, with a good habit; novel and quite distinct. Marchioness of Tweeddale, pure waxy white, fine habit, first-rate bedder.

Preparation for Winter.

THE present is a busy season of the year to the plant-grower and a press of work now requires immediate attention. One of the first things to be attended to is the housing of tender plants, as sharp frosts may be looked for at any time after the 1st of October. And for this reason it is quite time that Crotons, Aralias, Musas, Pandanus, Ficus, Acalyphas, and all other plants that are easily injured by frost, and that have been in use for bedding, vases and the like, should be brought under shelter. The Crotons should be cut back as they are brought in and potted up into as small pots as possible, and by keeping them a little close for a time they soon recover from the shock.

Some good cuttings are also secured in this way, the young plants from which may be grown on into useful size by the following spring. A few of the Acalyphas, when potted up and placed in a warm house, will yield an abundance of cuttings to supply stock for the following season, for these plants root as easily and quickly as Coleus, and for many purposes are much more effective.

Cannas may remain out-doors until the foliage has been marked by the frost, as one likes to enjoy these noble plants as long as possible, and the first light touch of frost will do no harm to the roots. It is well to save some seed of Cannas and sow it during the winter or early spring, as the seedlings frequently vary considerably from the parent plant. If the seed be selected from some of the improved varieties, it is quite probable that something of value may be secured among the seedlings.

If not already under cover, Carnations for winter blooming should now be lifted, a cloudy day being selected for the operation, if possible. If the plants have a good watering immediately after planting and frequent syringings for a few days they soon recover from the effects of removal.

The staking and tying of the Carnations may be deferred until the more important work of the season is attended to.

Bouvardias, Poinsettias, Heliotropes, Stevias and Eupatoriums will, of course, be under cover before this time, as these useful winter-flowering plants do not improve by being kept out-doors after the nights become cold. In fact, the Poinsettias are quite susceptible to cold, and soon become stunted and lose their lower leaves if they are chilled, and in this case, of course, the bracts produced are inferior in size.

The various bulbs for winter forcing will also be received about this time, or in some cases earlier, and should forthwith be potted or boxed, as the case may be. No time should be lost in potting up bulbs of *Lilium longiflorum*, so that their growth may be made steadily, and without unnecessary forcing, though it should be remembered that if the latter plants are required to be in bloom at Easter calculations must be made accordingly, and it must be borne in mind that next Easter will fall on a much earlier date than the last one. Lily-of-the-Valley, unless specially ordered for early forcing, will probably not be received until the last of October or beginning of November.

Some strong plants of *Deutzia gracilis*, and also some clumps of *Astilbe Japonica*, should be potted, since both these plants are particularly useful for white flowers during the latter part of the winter and early spring; but as both are perfectly hardy, they can, of course, remain in the ground until the more tender plants are disposed of.

Any necessary repairs, such as painting, glazing, etc., that have not been attended to during the summer, should be made at once, because the condensation of moisture on the roof of a greenhouse becomes much greater as the nights get cooler, and it is therefore more difficult to find the roof dry enough for such repairs than it would have been earlier in the season. On an old roof many leaks may be stopped by the application of liquid putty or thick paint with a putty-bulb. It takes but a short time to apply the liquid to each strip on a house 100 feet long, and the escape from drip thus secured is a great comfort for so small an outlay. A good mixture for this purpose is composed of equal portions of white lead and putty, mixed with enough good linseed oil to give the required consistency.

Holmesburg, Pa.

W. H. Taplin.

Spanish and English Iris.—These are the most common of the bulbous section of this genus and are very charming when grown in masses. The flowers have a good range of shades of yellow, bronze, blue and purple, and, being freely produced, the plants are in bloom for several weeks. While the bulb-dealers distribute a fair number of these bulbs every season, they do not seem to survive in gardens, or at least in those in which no care is given to the special requirements of plants. Bulbs of these Irises are hardy in a suitable position, and there should be success in growing them where their requirements are understood. In their native haunts they are subject to extremes of dryness and moisture, so they should be planted in a deep border, where in summer they will receive little or no moisture, and, if possible, a good baking. In winter and spring they will have moisture enough anywhere outside in this climate. Under the south wall of the house is a good position for these bulbs, and in such a place they do well with me, living and flowering freely. There is one point, however, which requires attention: the bulbs must be frequently separated and replanted, certainly as often as every other year; otherwise, as they break up so freely, they will overcrowd each other and starve out. Mr. Orpet's mention of these bulbs led me to look to my stock, and I find that last year's flowering bulbs have each thrown off four or five well developed offsets. These quickly came to flowering size.

Iris reticulata is another hardy bulb which requires a little care in placing, the main point with this being to plant it in a position where it will not start so early that hard frosts and high winds later will cut it off. Its fault is its precocity of bloom. This bulb forces readily, and its Violet-scented flowers are attractive though not very showy. Varieties of *I. reticulata* and allied species are now becoming numerous in cultivation and make interesting groups. Single specimens are not at all conspicuous. It would be interesting to know what proportion of the *I. Susiana* tubers, distributed every year by the bulb dealers, are flowered. This and allied species will by no chance succeed under careless treatment, as will many plants. It is usually recommended that they be planted in late winter in a cold frame. It should be added that in such a position they must have all the air possible. Good success can be had with them by planting in a warm border as late in the year as possible and mulching with six inches or so of

forest leaves. If planted early they quickly start leaves, and hard freezing or high winds are then fatal to their flowering. There is a world of interest in a general collection of hardy bulbs, and they are especially useful in a small garden, often enabling one to practically double crop valuable space.

Montbretia crocosmiæflora, the result of a cross between *Montbretia Pottii* and *Tritonia aurea*, produced by Monsieur Lemoine some ten years ago, has been a valued plant in many gardens since its first introduction, but apparently is not as widely distributed as it should be. Since the introduction of the first hybrid, Monsieur Lemoine has each year offered one or more varieties differing somewhat in the size of individual flowers, but principally in the coloring and markings, in a rather limited range of yellows and brilliant, warm, deep reds and their combinations. The effect of a mass of these flowers in the late summer is very distinct, neat and bright, without glare. In choosing varieties one can scarcely go amiss; the original hybrid being entirely satisfactory—and, of course, obtainable at the lowest price—while the more recent ones are all interesting, though the colors have such a narrow range that at a distance a casual observer would judge them the same; a flower fancier, however, does not collect for the casual observer. Color descriptions are unsatisfactory at best, and it is quite impossible to define shades of red (a color which many people cannot even distinguish), but of a few varieties under trial may be noted: *Pharé*, of a deep flaming orange-red; *Etoile de Feu*, a deeper shade, burnt orange; *Bouquet Parfait*, a slightly different shade of fiery red, and with larger individual flowers. These all have deep yellow eyes. *Elegans* is exceptionally distinct; clear yellow inside and splashed red without. The flowering habit of this variety seems specially graceful. A few others differ much on the same lines, and are all attractive. *Montbretias* need a well drained, deep and moist soil, in which the corms are usually hardy, though not always in this locality. They increase very rapidly, not only by multiplication from the parent, but by pushing out underground stems, from which new plants are rapidly produced. They also seed freely, and from this they will come into bloom in a few months. They are also neat plants for the decoration of the greenhouse in summer, as they grow away freely if not overpotted and bloom for a long season. Individually the flowers are not very lasting, but they are produced in rapid succession.

Elizabeth, N. J.

J. N. G.

Nymphaea Devonensis, though not new, may still be styled a novelty and has a special claim on our attention. While all other Water Lilies, with perhaps the exception of *N. dentata*, are past bloom for the season this is yet blooming freely, and is seen more now than at other times, because the flowers remain open during dull and sunless days while others are closed. This is truly an autumn flowering Water Lily. To prolong the season of this charming plant a shallow tank from twenty to twenty-four inches deep and any convenient size should now be in readiness to protect them in the latitude of New York, and earlier further north. I have nursery tanks twelve feet long, six feet wide and twenty inches deep. Plants grown in tubs and sunk in the Lily-pond are transferred to the tank, and an ordinary garden-frame with sashes can be placed over them. This protection will be sufficient to keep the plants flowering till the end of October. Other varieties can be protected in the same way.

Dongan Hills, Staten Island.

W. Tricker.

Figs in the Open Air.—The growing of Figs without glass in the northern states is not uncommon, and yet it was not until this summer that I saw them so grown for the first time in the gardens of Mr. H. P. McKean, of Germantown, and full of delicious ripe fruit. The only special treatment given in this instance is the burying of the trees when winter comes. The earth is thrown out on one side, the branches are bent over and kept down by stout pegs driven into the ground, and then the earth is thrown back to cover the branches to a depth of about six inches. These trees of Mr. McKean's are now about ten feet in height. On their north-east side a board fence has been erected to keep off cold winds in early spring and to give warmth to induce early growth. It should be borne in mind that they need a sunny place, otherwise some of the fruit will not have time to ripen before cold weather comes. It has been suggested that in planting, the roots should all be spread on one side only, so as to allow of the tops to be bent over in the same direction when the time for covering the tree arrives.

Germantown, Pa.

Joseph Meehan.

Clematis paniculata.—Allow me to add a word on the good qualities of this plant. I assume that it is correctly named,

although this has been disputed. However this may be, it has a vigor of constitution rarely found among Clematises not native. It blooms freely and late, and has a fragrance which resembles that of the Hawthorn as much as anything I can recall. It can be grafted readily on *C. Virginiana*, and also comes here from seed; but this is slow to germinate, although I think seedlings make rather the strongest plants.

Wellesley, Mass.

T. D. Hatfield.

[Not having seen Mr. Hatfield's plants, we cannot be sure of their identity. The note in our last issue referred to a plant which came from the Passaic Nurseries of H. Meyers, successor to Woolson & Co., and it is the true *Clematis paniculata*.—ED.]

Correspondence.

The Condition and Future of the American Forests.

To the Editor of GARDEN AND FOREST:

Sir,—I have never read anything which seems to me more graphic and true, and, at the same time, more lamentable, than the picture painted by Dr. Mayr of the condition of the American forests, and translated in your paper of September 10th. I venture to suggest that your Government, which does a vast amount of public printing, would render a public service by sending a copy of this article to every American citizen; for though it is not always pleasant to hear criticisms from a foreigner, and though it is not always possible for a foreigner to suggest a remedy or to appreciate fully the great difference which exists between the conditions of the American system of self-government and those of older countries, yet this question must be faced and dealt with before long.

The time will come when the names of those persons who have made it the business of their lives to bring home the condition of the national forests to the people will be honored as citizens who have deserved well of their country. The Russians have been described by an eminent German naturalist as "everywhere true wasters and destroyers of forests," but from what little I have seen myself in a single journey of about 10,000 miles through the United States, I do not think they can compare with the Americans; and speaking as an English farmer and as an Indian Tea-planter, who has seen in many parts of Europe and Asia the results of destroying the forests and skinning the land for the sake of a short-lived profit, I do believe that every foot of timber and every bushel of corn or wheat which you are sending us at a ridiculous price, will ultimately cost the American nation much more than their present value. Look at the present state of the forests and the land in many parts of the United States, and see what it will some day cost to restore the soil to a condition in which successful agriculture is possible, and consider what a poor return you are getting for this enormous present waste. What is the value of a few thousand Alaska seal-skins or a few ship-loads of Canadian fish compared to the value of the American public forests? and yet how much do we hear of the former in the debates of your Congress or in the speeches of your public men!

I cannot help thinking that the best possible remedy at present is suggested in your editorial article on "The Army and the Forests," and I can testify from personal experience of the success of this plan in the Yellowstone Park. When the British-Indian Forest Department was first created most of its officers were taken from the army, and though they lacked the technical knowledge, which is now supposed to be all-important, and to be gained only in the forest-schools of France and Germany, they had other qualities which are often wanting in the young men who now recruit the forest-service. For years to come the questions which will be most prominent will not be those requiring technical knowledge so much as common sense, tact and energy in enforcing the regulations which will be made after considering local needs and actual forest-conditions. And above all, you will find among the officers in the army men of such unimpeachable honesty that they will not be open to such criticisms and attacks as were formerly made upon the employees of the Indian agencies, and they will be removed from those political influences which seem to us to play such a prominent part in Government affairs in America.

From a soldier's point of view I would suppose that, considering the great influence upon the character of military operations which the wooded nature of the country has always had in the United States, an intimate knowledge of forest-operations and forest-life would be of more advantage to the American army than to any European troops. We know by experience that the *Ghoorkas*, who are bred and born in

mountain-forests and the best forest-workers we have in India, are also the best soldiers, and that their officers are among the most active and keen hunters in the Indian army. Quartered for the most part in detachments and out-posts on the frontiers, they live under very similar conditions to those which would be endured by detachments of troops engaged in guarding and supervising the state forests in America, and judging from what I have seen in the west I think that soldiers alone would be able to enforce the law in the Rocky Mountains under the existing conditions of society.

But it is not for me to do more than support, by such testimony as I can give, the very urgent nature of the questions which your paper was founded to discuss, and which it has so ably set before the public.

Cirencester, England.

H. J. Elwes.

Naturalization of American Conifers in Belgium.

To the Editor of GARDEN AND FOREST:

Sir.—The experiments which have been made in Belgium in the cultivation of North American conifers have been most successful. Unfortunately, such experiments have been unnecessarily expensive through the difficulty of obtaining good seeds, and I should be glad to establish friendly relations with reliable botanists and lovers of trees in the United States for the purpose of obtaining supplies of coniferous trees and seeds, and it is with this object in view that I address these lines to GARDEN AND FOREST.

We find in Belgium that the Douglas Fir grows most thriftily when it is planted in deep sandy soil in positions where it can be sheltered from severe winds during its early years in order that the shoots which sometimes grow late in the season may not suffer in the cold of exceptional winters. Many Belgian land-owners have planted this tree in large masses, and the way in which the most vigorous specimens here have flourished is exceedingly encouraging. Unfortunately, the young plants found in our nurseries have, in many cases, proved disappointing, and we need to be brought into direct communication with American seedsmen able to supply good seeds at reasonable prices. If this is done, there is hope of making this tree generally known in Belgium.

Abies balsamea is a pyramidal tree here, resembling somewhat the European Silver Fir (*A. pectinata*). It does not, however, attain the same size or live as long. In Belgium it reaches a mean height of forty-eight feet, and is relatively somewhat stunted in comparison with the other species of the genus; nevertheless, on account of its rapid growth in land underlaid with moist gravel, this species is not without value. I know of a plantation at Hastière, near Dinant, which is growing vigorously, and, although the specimens are planted too far apart, the terminal shoots are nearly three feet long, or sometimes more. I have no knowledge of the timber of this species. The straight, slender poles which it furnishes have, however, a considerable value.

A. grandis is a handsome and vigorous tree here, attaining in its native country a height of more than 250 feet, and a trunk diameter of four or five. It grows on flat lands with a humid subsoil and does not flourish in the mountains. The few strong, well grown specimens which I have seen in this country inspire hope of its successful naturalization in our plantations; indeed, the growth of this tree is very vigorous here, the terminal shoots attaining a length of nearly forty inches. Unfortunately, young plants of this species, as is the case with those of the Douglas Fir, are still quoted at such high rates that many planters are deterred from experimenting with them.

The California Mountain Hemlock (*Tsuga Pattoniana*), which attains in its native country a large size, grows at first very slowly in Belgium. When it is ten or fifteen years old, however, the plants begin to increase rapidly, and from that time forward they are very luxuriant, with terminal shoots more than a foot long. This species we find does best on hill-sides where the soil is light and deep. It bears our most severe winters, and, were it not for the scarcity and the high price of the young plants, it would be particularly useful for planting in groups in the sandy hill parts of Belgium.

The White Pine (*Pinus Strobus*) was introduced into France in 1705, and its value as a forest-tree here is now well known; indeed this species, with its luxuriant growth and tall trunk terminated by a majestic crown of foliage, has gained a notable position in our forests. It has the great merit of being able to grow in damp soil. I have seen specimens cut which were nearly eighty years old with a trunk diameter of three feet at the ground. Such trees have found buyers at an average price of \$25.

In those parts of Belgium where the soil is heavy and retains moisture the behavior of this Pine is also satisfactory, equalling that of *Pinus sylvestris*. We do not, however, know of any large plantations, the White Pine being always associated with other conifers such as *Pinus sylvestris*, *Pinus Austriaca* and *Larix Europæa*. It is often planted as an ornamental tree, and when fully exposed to the air and light it grows very rapidly. The wood is highly valued.

Pinus Sabiniana is with us still only an ornamental species; it grows well, but is still difficult to obtain from our nurserymen, and is always high-priced; nevertheless, the few specimens that I know are doing well. This California species should be more generally introduced into our forests.

Thuja gigantea and *Libocedrus decurrens*, both of which produce wood valuable for the cabinet-maker, would find ready buyers at remunerative prices. Unfortunately, they both grow slowly; at least such is the case with trees twenty-five years planted that I know here. They are not, perhaps, in proper soil or sufficiently sheltered. Their height is not more than twenty-five or thirty feet, with a diameter of trunk very large at the base in proportion to the height of the trees.

I believe that they are both valuable trees where time is not an important element, and certainly slowness of growth in a tree should not dissuade wealthy men, who can afford to wait, from experimenting with them. It is true of these California trees, as it is with Oak, the planter must know how to wait.

Nimy, Belgium.

Alfred Wesmael.

An Artificial Garden Effect.

To the Editor of GARDEN AND FOREST:

Sir.—There are growing in this neighborhood a couple of good-sized Beech-trees, which, by reason of their convenient location, are made to support a large double gate and to mark the entrance from a public road to a cultivated field. A number of years ago these trees were subjected to a close and general lopping off of their branches to within six or eight feet of their tops. The result of this operation was that the main stems, which in these instances were rather tall and straight, sent out innumerable sprouts from bottom to top. These new sprouts or branches seem to be of a uniform length of five or six feet, and with their uniformly heavy coat of leaves, form a towering and dense mass of foliage as nearly true and symmetrical in outline as if cut to a model. At a little distance it is suggestive of great masses of vines dependent from the (concealed) limbs of tall stumps. The effect is a most striking one, and can lay claim to elements of beauty essentially its own. But it is in the winter season they present the most remarkable effect. A peculiarity of the new shoots is that they tenaciously hold their leaves, and while the only change in the general aspect is in the coloring, the trees necessarily stand out more prominently and become more marked features in the winter landscape.

The owner's only object doubtless in despoiling those trees was to secure a couple of convenient gate-posts, while he got rid of their offending features in shading valuable ground. But he secured at the same time a unique piece of ornamentation which does not appear in its artificial features inconsistent with the general design of a gate-way entrance to cultivated grounds.

In the facts here given is there not a hint of what might be accomplished in certain possible contingencies in producing garden effects? As when a tree is out of place or is not wanted, or an artificial effect is desired or justified, and especially when it is wanted to produce a winter effect. I have long observed that the second growth of branches, or the shoots which result from a general cutting away of the original branches of certain trees, have a tendency to hold their leaves well on into the winter. It need scarcely be added that none of these new branches or sprouts, by reason of their great number, are likely to develop into large limbs, and therefore the resultant shape of the tree is practically permanent.

Fairview, W. Va.

W. E. Hill.

The Fay Currant.

To the Editor of GARDEN AND FOREST:

Sir.—I observe some discussion in regard to the merit of Fay's Currant as compared with the Versailles. The Cherry and Versailles have been the leading red Currants for years owing to their superiority in size over the Red Dutch, Victoria and other red sorts. The Cherry is notoriously a poor bearer, producing much blind wood—that is, wood without eyes or fruit-buds. This defect seems to vary in the same plants in different seasons, but the fruit is large, handsome and attractive, and it meets with popular favor.

The Versailles produces fruit fully as large as the Cherry, and, I think, sometimes a little better in quality and more of it. Occasionally it carries too much blind wood, and thus demonstrates its nearness of kin to the Cherry; but this is not a serious fault.

The Fay Currant is much more productive than the others; the fruit is quite as large, and the quality is no way inferior. It has the fault, however, of a procumbent tendency. The plants seem determined to develop a trailing habit, very different from that of the erect Versailles. Many of the shoots starting from the base of the plant will run out on the ground and curve up their ends a few inches high, a habit which I dislike very much; and yet I shall set more of them. Of late years we have seldom secured full and perfect clusters of this fruit, because the unfavorable weather at the time of blooming, or some other cause, has prevented the later blossoms from setting. The clusters, therefore, are only about half as long as nature intended them to be. But after all, the Fay seems a great step forward in the development of this fruit, although the ideal Currant has not yet been produced.

Montclair, N. J.

E. Williams.

Recent Publications.

A recent issue of the *Bulletin of Miscellaneous Information* issued by the authorities of the Royal Gardens, Kew, contains an important paper upon the *Fibre Industry at the Bahamas*. It appears from a report of the United States Consul at Nassau, reproduced in the Bulletin, that the progress made in the development of Sisal culture (Sisal hemp being the product of a species of Agave—*A. rigida*, var. *Sisaliana*) during the past twelve months has been marvelous. A year ago there was scarcely a dollar of foreign capital, and very little local capital, invested in this business in the Bahamas, while to-day capitalists from Great Britain, Canada and Newfoundland are buying up Government land by thousands of acres, and are setting to work industriously in clearing and planting as fast as they are able to procure plants for the purpose. Mr. McLain, our Consul, writing on the 20th of January last, reports:

"Small shipments of fibre continue to be made by nearly every steamer, a few old plantings furnishing the material. It is not likely that shipments in any quantity will be possible under two years, but after that time an enormous increase may begin to be looked for, increasing steadily as new fields come into bearing, until the annual exports of the colony, which now average about \$600,000, will leap well up into the millions, as a moment's reflection will show.

"It is a very low estimate to expect half a ton of fibre per acre, and a very low estimate to call it worth \$100 per ton, for it is worth over \$200 per ton in the world's markets to-day. When even the present quantity of land sold and applied for, to wit, 300,000 acres, is bearing, which ought to happen within five or six years, it will produce 150,000 tons a year, worth \$15,000,000, an increase of prosperity that sounds more like a fairy tale than a strong probability deduced from reasonable figures. And yet 300,000 acres is but a small portion of the uncultivated lands within the limits of the Bahamas.

"It is estimated that about 6,000 acres of land have already been planted in Sisal (a plantation once started needs no replanting for many years), and that many additional ones have been cleared and made ready for the plants, the obtaining of which has been almost impossible, the industry being seriously retarded thereby. The prices paid for plants have risen from six cents per dozen to thirty-six cents, so great has been the demand; but the price will now decline rapidly since the supply of plants is developing enormously, about 2,000,000 being now available for planting and others coming on speedily.

"The Pita plant is being found on all the islands growing wild, and the stock of old plants is very great. From the centre of the old plant rises a pole about sixteen feet in length, on the branches of which small plants grow, averaging a thousand to each pole, and from these poles a vast supply is coming into market, creating a profitable business; for what were two years ago only noxious weeds have all at once become worth \$20 apiece for pole plants alone. Quantities of old plants have lately been discovered growing on the keys along the Florida coast, and small schooners are already buying these up and bringing them here for sale. This fact suggests the question whether this new hemp industry, which is about to revolutionize the condition of the Bahamas, may not also be developed in the southern portion of Florida. The plants are found there growing wild just as they are in these islands, and they flourish best in dry, sandy soils fit for little

else. I would earnestly call the attention of the Department of Agriculture to this matter, and suggest the propriety of looking into it, and of calling the notice of the people of Florida to this possible source of wealth and prosperity. The conditions of soil, climate, etc., which make its culture a success here, may not obtain there, but the simple fact that the plant is growing wild in Florida is of itself a consideration that should warrant an investigation at the hands of the Department.

"There can be no doubt or question as to the success of Sisal culture in this colony. It has passed far beyond the experimental stage, and is giving daily evidence that it will become a source of wealth to all concerned. The combined conditions of soil and climate especially adapted to the growth of first-class fibre give this colony a marked advantage over other West Indian islands, where the plant may grow luxuriantly enough, but will be found deficient in good strong fibre. The poorer and more sterile the soil the better the result, and here the plant flourishes where ordinary vegetation seems almost impossible. It is a plant of unfailing growth, it will live without rain to moisten the soil, you can scarcely exterminate it if you try, it requires but little cultivation, and at an expense below that of almost any other agricultural product, and its value is substantial.

"As two-thirds of the trade of the Bahamas is now with the United States; as their only steam communication with the outside world is by a subsidized line of American steamships running between Nassau and New York; as their increased wealth and prosperity means a larger and more profitable commercial intercourse with our own country, we should view this coming development of their material interests with pleasure, and with the warmest wishes for its complete success."

Meetings of Societies.

Horticulture in New Jersey.

THE fifteenth anniversary meeting of the New Jersey Horticultural Society at New Brunswick last week gave occasion for a brief review of the Society's work and history by Secretary Williams, from which it appeared that the horticulture, and especially the fruit production of the state, owe much of their prosperity to the educating influence of this organization. Members of this society have been among the first to make practical use of scientific discoveries in the study of possible remedies for plant diseases and the ravages of insects; some of them have won honorable distinction. On one of the tables there was an exhibition of pears by Mr. White which bore witness to the efficacy of modern treatment against Fungus. One tree which had been left unsprayed lost all its fruit and foliage by Fungus (*Entomosporium maculatum*), while on the trees treated the fruit and foliage was nearly perfect, and they would probably have been quite so if the spraying had not been discontinued so early. These fruits were an object-lesson to all, and they showed the great advance that has been made in spraying compounds and machines.

The only incident that marred the pleasure of the meeting was the resignation of Secretary Williams, who during the entire life of the Society has labored with untiring zeal for its advancement. The continued ill health of Mr. Williams has compelled him to take this step. The regret at his determination was unanimous, and the resignation was referred to the Executive Committee in the hope that when the time for the annual meeting came round in December his health may be sufficiently improved to warrant his remaining in the service. There are few men in the country whose influence has been more widely felt in the direction of improved horticulture and none whose retirement would be more lamented by the horticulturists of the country. Mr. Williams is a man of singularly pure and honest purpose, and he has no superiors in practical knowledge of the particular branches to which his attention has been directed.

Newark, N. J.

J.

Notes.

"*Primula obconica* poisonous" has so frequently been the heading of articles in many horticultural journals, foreign as well as American, that the irritating qualities of the plant may now be considered proved beyond a doubt.

A very beautiful colored plate of *Shortia galacifolia* was issued with *The Garden* for August 30th, accompanied by an abstract of its romantic history, drawn from the longer account which was published in GARDEN AND FOREST nearly two years ago.

Mr. H. B. Ayers reports the discovery of the Hemlock in Section 10, Township 48, Range 16, Carleton County, Minnesota, thus extending the range of this tree further west than it has been before reported, western Wisconsin having up to the time of Mr. Ayers' discovery been considered its western station.

A new Carnation with unusually distinct stripes of red and white has been sent to this office by Messrs. Peter Henderson & Co. It is said to have originated with Mr. George Bergman, of Flatbush, Long Island, as a sport from Portia, which will account for the vividness of the red in its marking. The flower is very fragrant, and it has been christened The American Flag.

The report of the Botanist of the Nebraska State Board of Agriculture, Dr. Charles E. Bessey, is an admirable monograph on the Grasses and forage plants of that state. Mr. Herbert J. Webber, the Assistant Botanist, adds a "Catalogue of the Flora of Nebraska," which is valuable not only for its facts as to the distribution of the Grasses, trees, shrubs and other higher forms of vegetation, but also for its account of the Fungi and other lower plants, many of which are of direct economic interest to man. Of Grasses proper there are enumerated 106 wild species, besides twenty-two which have been introduced purposely or otherwise by man and have subsequently "run wild" to some extent.

The place which Tuberous Begonias have gained in popular favor is shown by the fact that an English journal recently spoke of a nursery garden where about 200,000 of these plants were growing, all this year's seedlings. Although the season has not favored them, the writer says: "There are many superb flowers in the open ground, but it is upon the plants in pots that the grand flowers are to be seen. Among the white and yellow varieties the greatest improvement appears. Plants with a drooping habit, eminently suited for hanging baskets, are here to be seen heavily laden with bloom, whilst the large pot plants exhibit the point which Mr. Laing had before him in the improvement of the Begonia—namely, erect flowers which can be seen without raising them."

Monsieur Carrière describes and illustrates in the September issue of the *Revue Horticole* a new hybrid Rose produced by a gardener near Paris by crossing the Japanese *Rosa rugosa* with the well known Hybrid Perpetual Madame Abel Carrière. This new addition to the Rose garden is described as a vigorous shrub, forming a stout bush five or six feet high by as much in diameter, with handsome dark green, lustrous foliage and flowers produced in large many-flowered corymbs. They are semi-double, with white or pale pink petals, and the curious thing about them is that the petals are conspicuously and deeply notched or fimbriated at the summit, a peculiarity to which the plant owes its name, *Rosa rugosa fimbriata*. It is described as a continuous bloomer, producing flowers from June until October.

The *Revue Horticole* says: "An idea which at first seems bizarre and a little facetious, but is at bottom very sensible, has just been suggested by GARDEN AND FOREST. This is: that hair-pins may be used to fasten to the ground the branches of border plants. The advantages offered by these little instruments, which thus far have had little enough to do with horticulture, are increased by the fact that they are manufactured of different degrees of length and thickness. These new hooks are very strong, and, moreover, very inconspicuous, and modern methods of manufacture render them very cheap." We may add that the neat little bundles in which they are sold seem to make them so convenient to carry, that no gardener need ever be without an immediate remedy for a wayward shoot.

A scheme is afoot for converting the banks of the River Lea into boulevards for the recreation of the inhabitants of East London. It is proposed to acquire strips of land extending for twelve miles and to lay them out as parks, cricket-fields, etc. "The idea," says the *Gardeners' Chronicle*, "is really a somewhat tremendous one, but the most careful inquiry and calculation have led us to the conclusion that it is not only perfectly feasible, but may be carried out to the letter. The advantages to be gained in many ways are simply incalculable. Much of the land is absolutely valueless under the present condition of things. This course, which will unquestionably take effect sooner or later, will not only transform a dull and dangerous part of the country into a series of charming boulevards, but will have the effect of immediately enhancing the value of the property in the vicinity."

In the *Journal of Mycology*, published by the Department of Agriculture, Miss Southworth writes of a new disease of

the Hollyhock quite distinct from the well known Hollyhock disease (*Puccinia Malvacearum*), or from the spot disease described by Professor Halsted in the issue of this journal for March 26th, 1890. The trouble made its appearance five years ago, and has proved so destructive where Hollyhocks are grown for bedding purposes that the price of the plants has quadrupled in New York during the past two years. The Fungus attacks leaf, petiole or main stalk; the flow of sap is stopped and the parts of the plant beyond the diseased portion shrink and die. Treatment with the copper solutions was not completely successful this year; but a thorough spraying with Bordeaux mixture on both sides of the leaves as soon as the young ones appear, and again later, should be tried next season. Of course, all diseased plants should be removed from the green-house, and whenever practicable the plants should be grown out-of-doors.

The death of Miss Marianne North, which occurred recently at her home in Gloucestershire, in England, closes the career of a woman of remarkable energy, courage and perseverance—the greatest traveler of all her sex, perhaps, and a charming and sympathetic personality. Ample means and abundant leisure made Miss North a traveler, and a traveler whose journeys produced visible results, which have served to instruct and delight the world. Long ago she formed the idea of turning her skillful brush to good account, and all her later and most difficult journeys were undertaken for the purpose of transferring to canvas the most remarkable and interesting aspects of the vegetation of the world. To do this she visited the forests of Brazil and California, the mountains of Peru, New Zealand and Australia, the East and West Indies, China and Japan, northern and southern Africa, the Himalayas and wherever else English enterprise had gained a foothold. Such journeys are in themselves difficult, hazardous and fatiguing, and when they are accompanied by the exposure and strain attendant on the labors of an artist painting from nature, often under the most severe conditions of climate and surroundings, they tax the strength of mind and body to the utmost limits of endurance. Four or five years ago Miss North went to Chili for the express purpose of obtaining pictures of the remarkable forests of Araucaria which are found there only on some of the highest mountains. But her constitution, weakened by long residences in the hottest and most unhealthy parts of the world, gave way under this new effort. A long rest in the healthy climate of the mountains of Jamaica failed to restore her wasted energies, and she was forced to give up a proposed visit to Mexico (almost the only part of the world she had not seen) and return to England, which she was not destined to leave again. The enjoyment of her last years, clouded by long and painful illnesses, was found in gardening, to which she became enthusiastically devoted, and which she carried on with great success. Miss North presented her most important works, illustrating various aspects of vegetation, to the British nation. They represent a series of nearly six hundred pictures, which are preserved in the "North Gallery," which she caused to be erected, at her own expense, within the Royal Gardens at Kew, where it forms one of the most instructive and popular departments of that great establishment. Miss North passed a summer in the eastern states many years ago, residing for a considerable time on the north shore of Massachusetts Bay. The friends whom she made in this country at that time, and those who have been fortunate enough to enjoy the hospitality she dispensed so charmingly in London or at her last home at Alderley, remember her with admiration and affection.

Catalogues Received.

F. E. McALLISTER, 22 Dey Street, New York; Bulbs and Seeds.—JOHN GARDINER & Co., 21 North Thirteenth Street, Philadelphia, Pa.; Spring-flowering Bulbs and Roots.—T. S. HUBBARD & Co., Fredonia, N. Y.; Grape Vines and Small Fruits.—F. SANDER & Co., St. Albans, Eng.; Orchids.—HARTMAN MANUFACTURING COMPANY, Beaver Falls, Pa.; Wire Specialties.—WM. PARRY, PAIRY, N. J.; Fruit, Ornamental Trees, etc.—PETER HENDERSON & Co., 35 Cortlandt Street, New York; Autumn Bulbs, Plants and Seeds.—S. C. DE COU, Moorestown, N. J.; Small Fruits and Plants.—VILMORIN-ANDRIEUX & Co., 4 Quai de la Mégisserie, Paris, France; Seeds and Bulbs for Autumn Planting.—JOHN R. & A. MURDOCH, 508 Smithfield Street, Pittsburgh, Pa.; Trees, Bulbs and Flowers.—CURRIE BROTHERS, Milwaukee, Wis.; Flowering Bulbs, Plants, etc.—AUGUST RÖLKER & SONS, Station E, New York; Select Flower Seeds.—SIDNEY TUTTLE & Co., Bloomington, Ill.; Trees, Plants, Shrubs, Roses, Bulbs, etc.—ELI WANGER & BARRY, Rochester, N. Y.; Pot-grown and Layer Strawberries, and Novelties and Specialties for Fall Planting.

A Park Association.

THIS is peculiarly an age of organization. In nearly every branch of science, of trade, of industry, and even of sport, we have national associations meeting in annual conventions. These associations have, for the most part, proved to be powerful instrumentalities for the promotion of their particular ends. They bring men together for the interchange of ideas upon subjects of mutual interest; they give to men living in widely separated parts of the country the advantage of personal contact with each other, and they provide the opportunity for agreement upon concerted lines of action to forward the ends they have at heart. There is one great popular interest, however, in which, as yet, no steps have been taken toward organization. That is, the important service of public parks. It is time that some action of the kind were taken. The public park movement now extends to nearly all parts of the country, and popular interest in the subject was never before so great. By organization this movement can be greatly assisted, and much can be done toward making the popular interest more active and intelligently effective.

Most of our leading American cities have now important park undertakings in hand, and many of the smaller ones have become alive to the value of public pleasure-grounds, and have taken practical steps to secure them. The formation of a public park association could hardly fail to make this movement still more widespread and to increase the popular interest in the subject. The publication of the proceedings of such an association, and their discussion in the press, would have a marked educational effect upon the people. The true purpose of parks would be more widely comprehended, and the danger of their abuse and maladministration would be correspondingly diminished. The meetings of the association each year, now in this city, now in that, would advance the park interests in the various localities. The several great cities of the country would each desire to be honored with a meeting of the association, and there would be a friendly rivalry among them in the matter of worthy preparation for the event.

Each would desire to have its parks made most attractive for the occasion, special attention would be given to the subject, and the improved aspect of the pleasure-grounds of the city would be likely to be so marked that a subsequent falling off would be more difficult, and the result would be a permanent improvement. A spirit of emulation would also induce cities that had not yet given attention to the subject to undertake the establishment of public parks.

We would, therefore, suggest the formation of an American Public Park Association, to comprise the commissioners, trustees or committees in charge of the public parks and pleasure-grounds of the various cities and towns, also the authorities in charge of national and state parks or reservations, such as the Yellowstone and the Yosemite, the Niagara Falls, and the proposed Adirondack reservations in New York, and the proposed White Mountains reservation in New Hampshire. Organizations like the Massachusetts Trustees of Public Reservations, the proposed body in Massachusetts for the preservation of beautiful and historic places, should also be included, and an indispensable element in the membership would be the landscape-architects or gardeners engaged in park work, and also the superintendents of public parks and pleasure-grounds.

It would be well to make the Association continental, rather than national, in its scope, after the plan of the American Association for the Advancement of Science, the American Forestry Association and other important bodies. It would thus include not only Canada, but also Mexico, for in the latter country the institution of public pleasure-grounds, particularly in the shape of urban gardens, is a universal one, and much could be learned in that quarter. Appropriations from the various municipalities to defray the expenses of officials attending the meetings of the Association would be eminently proper, for the advantages gained from such conferences would return the expenditures manifold.

The meetings of the Association could not fail to be occasions of exceptional interest and enjoyment. They should be held annually in the various large cities of the country where public parks have been established, at some favorable time during the pleasant seasons of the year, ranging from late spring to early autumn. Perhaps, owing to the peculiar nature of the object, it might be well not to have the time for meeting fixed for any special week, or even month, since an examination of the parks of the place of meeting would be one of the features of the occasion, and therefore the time most favorable should be chosen. The time of year which would be most favorable for meeting in a Canadian city, for instance, might be extremely unfavorable in a southern city. It should also be the aim to hold the meetings successively in widely separated portions of the country, in order to make the influence of the Association as extensive as possible, as well as to give an agreeable contrast of environment to the various gatherings.

The subjects for discussion would have a wide range of character and would be practically inexhaustible. They would include questions of the maintenance, the management and the use of parks, and of their adaptability to various purposes. Landscape-gardening, with all its possibilities and limitations, would always furnish themes for discussion. Much information could be imparted and learned by means of lantern-slide exhibitions illustrating notable works completed or in progress. Visits to the parks of the city where the meetings might be held, besides excursions to places of scenic interest in the neighborhood, would all help to make these conventions events of educational value.

The power for good proceeding from such an association would be noteworthy in bringing about better methods of administration, in extending the influence of men who are recognized masters in the art of park design, and in elevating and popularizing the standards of good taste, and in checking meretricious and evil tendencies.

It might also, be desirable to supplement the American Association with minor organizations of a sectional character, as in states like New York and Massachusetts, for instance, where public parks have of late years become numerous. In Massachusetts there are now at least nine cities and towns with boards of park commissioners. Besides the great park system of Boston, the parks of Lynn, Brookline, Worcester and Lowell are undertakings of notable importance. A state park association would therefore be capable of doing much good in the way of forwarding the right kind of legislation and in disseminating enlightened views on the subject.

Names for County Roads.

A SYSTEM of numbering country houses has been started in Contra Costa County, California, which, through the exertions of its originator, Mr. A. L. Bancroft, has attracted comment all over the country. Perhaps the most characteristic feature of this scheme is the so-called "ten-block system," according to which each mile along the various roads of the county is divided into ten equal parts or imaginary sections of 528 feet, and to each block is assigned an even number on one side of the road and an odd number on the other. Any house located within the block bears its number, and where a block contains more than one house these are distinguished by letters. Of course these numbers will indicate the distance from the starting-point, so that there is no trouble in calculating how far any given house or block is from any central point where the numbers begin, as, for example, from the county-seat, and, indeed, from any other point in the county by a given road. Numbers placed at the entrances of the various houses would in this way serve as mile-stones also, and the scheme taken all together contemplates the publication of a county directory on the same plan as that of the city directory.

The need of such an accurate location of one's dwelling place does not seem to be so great in the country as in the city, and perhaps it will be some time before the county directories will become general. But before the roads can be divided into blocks they must be named, and if any system of numbering is to be of benefit to strangers there must be guide-boards containing these names. This naming of the country roads, however, could be adopted in any county, even where the remainder of the organized plan was not adopted. The people of the particular county where this innovation has started have acted with remarkable good taste in the selection of names for their roads, and in an article which appeared in the *Pacific Rural Press* some months ago some admirable directions for naming roads were laid down. Here are some of them: A road should not be named after a residence or the name of a farm on it, since this would not be satisfactory to those whose names were not selected. A road should not be named after either of its termini; for while this might be appropriate in traveling in one direction it would be inappropriate in going in another. Names should be sought among the legends, the historical associations, the botanical characteristics and landscape features of the locality. If it is found difficult to select enough names of this sort good taste would suggest others hardly less appropriate.

In Contra Costa there is a foreign population of some size, and foreign names are used in some cases. The word road is not invariably adopted, but some other equivalent has been substituted. Some of the names selected are here given: The Contra Costa Highway is the road leading from the county-seat through the county; and as this is the only road which is called a highway it will be known as The Highway or the principal road of the county. Rio Vista or River View is the name of the road along the bluff that overhangs the river. Mountain Drive designates the road that leads to the summit of Mount Diablo, and Camino Diablo the one which winds around its base. Via Concordia is a road near the town of Concord. Willow Pass Road runs through the pass so named and extends both

ways. Lime Ridge Crossing is the road which runs over this ridge, connecting two other roads, one on each side. Walnut Way is a road through a region where the native California Walnut-trees are numerous.

These examples show how admirably the work of naming has been done, and if tasteful guide-boards, painted with a light, though not white, background, and a dark border, and lettered with dark brown, are used, the general effect will be very pleasing. The name, however, is the essential point. Sections of the country where every farm and every feature of the land are known by some characteristic and distinctive title are invested with a peculiar interest. No one ever heard the name of the Hawk's-Nest Road, which runs along the brow of the cliff that overhangs the Delaware River above Port Jervis, without a desire to ride over it. And pleasant as is the prospect from Wolf-Pit Hill, looking down "The Clove," in Wantage township, New Jersey, it has an added charm from these names, which were given by the early Dutch settlers of the place.

Jeannette Park, New York.

THE city of New York is not well furnished with small parks, but one of the most interesting of these is illustrated on page 503 of this issue. Although it is in the oldest part of the city, and in a part devoted to the heavy business which naturally establishes itself along the docks, it is a very new park, the space which it occupies having been provided by the filling in of Coenties Slip, which, until a few years ago, extended inland from the river front through the entire depth of the square. Four years ago it was decided by the Park Department to plant the small area which was thus added to the territory of the city, and a plan was prepared by Mr. Samuel Parsons, Jr. As the park is not a thoroughfare, and there is no occasion to cross it in a direction parallel to the river, there are only two entrances, one on the side fronting the river and the other opposite to it. The view, which is taken from the roof of one of the houses facing the park, gives its design as clearly as if it were a map. The area of the park is about two-thirds of an acre, and the plan is simply an exterior border of shrubs, with occasional loose groups and masses of shrubs and herbaceous plants within the path, while at considerable distances apart are planted American Lindens, Elms, some Lombardy Poplars and occasional specimens of the Purple-leaved Plum.

In the older parks this view of the turf from above would not be possible, owing to the spreading tops of the trees. But here the trees have not yet reached a sufficient size to obstruct the sight or to be of any value for shade. It is worth while to note, however, that the only way in which it is practicable to obtain thrifty masses of shrubs among trees is to plant them together, so that they can adjust themselves to each other's company as they grow. After the trees are once established it is almost impossible to induce shrubs to grow in the shade of their branches. The shrubs used here are mainly Bush Honeysuckles, Thunberg's Barberry, Philadelphus, Japanese Snow Ball, Japan Quince, Coral Berry, Weigelia and Japanese Privet. This last plant, although it grows in rather a whippy form, can be kept in good shape by hard pruning, and it endures the trials of city life as well as almost any other. It is largely employed in this park. Besides these, there are some Golden Elders, which have been carefully pruned, and have this year been unusually rich in color.

This little bit of green is particularly cheerful in the closely built business part of the city. Its lines are all graceful; the selection of shrubs is good; the turf is in admirable condition, and as seen every day by the thousands who pass by it on the elevated railway, and get about the same view as the one in our illustration, with the busy river beyond and the Heights of Brooklyn in the misty distance, it is a pleasing and refreshing picture. It is a matter of complaint by the boys that they cannot play base ball in Jeannette Park; but it is an unfailing delight to their smaller brothers and sisters, and in summer evenings it is

filled with people who live in the few flat-houses in the vicinity and in the upper stories of the warehouses and business buildings. It should be added perhaps that in the perspective the true shape of the park is hardly apparent. It is nearly twice as wide at the side next to the river as it is on the opposite side, and no two of its boundary lines are parallel.

A Japanese Floral Calendar.

IF a visitor to the City of Tokio should walk up along the Sumida River he would find upon the bank a noted garden which is known here by the name of Hanayashiki, which means in the Japanese language The Garden. To one who enters there to sip a cup of tea a little maid will present a printed list of flowers classified in the order of the months, and it will be found that the list is adapted to the Chinese calendar as most of our garden plants and our art of gardening were derived from China. The first month of the Chinese, which is the Japanese horticultural and floral January, begins about the middle of February in our modern calendar, and so on during the course of the year, and readers will understand that the first month on the list means February, and that the February of the horticultural calendar means actually March. Here are the seven chosen herbs of January: (1) Seri, *Cenanthus stolonifera*; (2) Nadzuna, *Capsella Bursa-Pastoris*; (3) Hakobe, *Stellaria media*; (4) Suzushiro, *Arabis flagellora*; (5) Hotokenoza, *Lamium amplexicaule*; (6) Suzuna; (7) Gogiyo.

These are the flowers of spring, the seven herbs being the earliest growth after the severe cold and deep frost of the winter. In the garden named above in the spring we can call for the soup of the season, which contains all these herbs. In a well ordered family the good housewife would prepare water with Nadzuna in it, and in this water the members of the family would dip the tips of their fingers before they pared their nails, which have been allowed to grow since December. This custom, however, is becoming obsolete.

After February, when the days become longer, the most popular flower is *Prunus Mume* (the Mume of the Japanese), which is generally cultivated throughout the empire both for its flowers and its fruit. The beauty and fragrance of its rich varieties are indeed worthy of admiration. It is often kept in a dwarf condition, and under this treatment is suitable for pot-culture on the porches or verandas. With it is found the indispensable and beautiful yellow *Adonis Amurensis* (the Fukujiso of the Japanese). The fruits of this tree make a very useful condiment, and its acid is extensively used for dyeing and other industries. The early Cherry, *Prunus subhirtella* (Higansakura), with its later varieties, blossoms in March, at which time the whole country is gay with merrymaking and excursions, and people of every class and age go out to enjoy the splendid display which Nature makes. Hundreds of people now repose on the smooth turf; and the soft sunshine and genial air are excelled in no other holidays of the year. In Japan the fruits of this Cherry are not cared for, but the flowers only.

On the eighty-eighth night after the 1st of January farmers rouse themselves from their winter confinement and leisure and begin to sow seeds in the fields and make beds in the gardens for their new plants. The Nashi (*Pyrus Ussuriensis*) is now in full blossom, followed by the famous Botan (*Paeonia Moutan*), which is well known in foreign lands, and in which we take a pride second only to that which we feel in the Chrysanthemum. Flower shows are held all over the country during this season. Less widely known than the former, and yet a general favorite here, is Shakuyaku (*Paeonia albiflora*), which has been favored by Nature with an air of gaiety beyond that of any of her floral companions. In one of our well known verses it is said:

"Slender and shy like Shakuyaku when she stands;
Beautiful and dignified like Botan when she sits;
As stately and gentle as Yuri (Lily) in her bearing when she walks;
These graces I hope for in her."

Sendan (*Melia Japonica*) and Unohana (*Deutzia Sieboldiana*) are not so attractive as the plants already mentioned, but the latter is used by good women in their celebration of Buddha's birthday on the 8th of April just as the Holly is among Christians.

At the end of May comes what we call the "Little Summer," really the approach to summer, when the Hanashobu (*Iris laevigata*) and Nemunohana (*Albizia Julibrissin*) are in bloom. Then comes Asagao, which means, in the Japanese language, Morning Face, as you say in English, Morning Glory (*Ipomoea hederacea*), to which special attention is paid by the

park gardeners of Tokio; and along the moat around the old castle of Tokio the morning walk is made beautiful by the blooms of Hasu (*Nelumbium speciosum*). *Scirpus maritimus* is another famous plant of the season, and in July, when the morning fogs leave dewdrops on the wayside grass, the *Lespedeza bicolor* in its varieties, some violet and others white, is abundant everywhere.

July and August are the most important floral months, and altogether the richest in the calendar in Japanese flowers. Here is a set of seven, which is usually offered on the festival of the Milky Way held on the 7th of July: (1) Senno, *Lycnis Senno*; (2) Hayakiku, Early Chrysanthemum; (3) Kikiyo, *Platycodon glandiflorum*; (4) Ominaeshi, *Patrinia scabiofolia*; (5) Hasu, *Nelumbium speciosum*; (6) Oguruma, *Inula Britannica*; (7) Shimagaya, *Phalaris arundinacea*. Another collection for August is very useful and popular, in which we find two or three of the plants included in the last set: (1) Karukaya, *Anthisderia arguens*; (2) Kikiyo, *Platycodon glandiflorum*; (3) Ominaeshi, *Patrinia scabiofolia*; (4) Hagi, *Lespedeza bicolor*; (5) Shiwon, *Aster Tartaricus*; (6) Fujibakama, *Eupatorium Chinese*; (7) Kudzu, *Pueraria Thunbergiana*. But there are often arbitrary amateurs who discard *Pueraria Thunbergiana*, and even *Aster Tartaricus*, for *Ipomoea hederacea*. The list we have made is the one popularly followed. The plants are generally grown together, not in regular rows, however, but in apparent confusion, so as to bring out their harmonies and diversities as in their wild state.

Two weeks ago I went for a trip to the north, and found some of these flowers growing in Nasuno, one hundred miles from Tokio, on the way from Nikko to Shiobara, in their finest natural forms.

September is the month of the Chrysanthemum, and exhibitions of these are held in various places. One of the largest and finest is in His Imperial Majesty's detached garden at Aoyama, Tokio. But it is impossible to give any idea of the abundance and beauty of our national flower at this season.

In October comes the early frost, when the leaves begin to change their color and thus invest the mountains beyond the suburbs of the city with new beauty. The trees are chiefly Momidji (*Acer palmatum*) and its varieties, Urushi (*Rhus vernicifera*) and *Ginkgo biloba*, with which the Japanese floral year is concluded.

In the two months which follow *Pinus densiflora* (Akamatsu), *Thalictrum aquilegifolium* (Kamakurahiba) and similar evergreens rule in the gardens of the country whose people cannot do without them at any season. Indeed, this rich and fertile empire is ever green with foliage, and the happy mountains and valleys have a smile for visitors even in the middle of our hard December.

Of course, what I have written is not meant as a list of the plants available for garden purposes in Japan, but simply a catalogue of those which are kept in Hanayashiki for the purpose of indicating the respective seasons. Besides these, we have special exhibitions of Camellias, Wistarias and Azaleas at various places, of which I hope for an opportunity to describe later.

Agricultural College, Tokio, Japan.

H. Yoshida.

Nematodes in the Chrysanthemum.

COMPLAINTS of sick Chrysanthemums have been so loud and general this autumn that a microscopic inspection of the trouble has been undertaken. The plants fail to make any adequate growth, the lower leaves turn brown and dry up, and soon the diseased plant is uprooted and replaced by another, which in its turn dies after the same fashion. With the hand lens no signs of insects were to be seen and no form of mildew or rust was found. But when the leaves in the first stages of the trouble were torn to pieces with a needle and forceps in water it was found that all the pulpy portion was infested with minute worms. They were found of various sizes and ages and in great numbers. Upon examining the dead portions of the plant the remains of these same worms were detected in all stages of decay.

The species is a Nematode which seems to be the same as that which was found on Violets last winter, and also at the present time, as some growers have recently reported. In the cultivated Violet the worms are practically confined to the roots, where they produce galls in considerable numbers, easily seen with the naked eye. *Heterodermia radiculicola* is charged with preying upon a large list of cultivated as well as wild plants, but the works upon the subject do not mention the garden Chrysanthemum among the victims. If the Nematode in question is the same as that now well known upon the Violet it suggests that these two plants

should be kept at some distance from each other, or, at least, that earth once used for Violets should not be employed afterward for Chrysanthemums. Remedies for the Chrysanthemum Nematodes do not seem easy of application. A leaf, for example, that has lost its green color, and is passing through various shades of yellow to brown, may be alive with worms, but they are out of the reach of any external application, while lime or lime-water applied at the roots does not reach the place where they are most active.

Of course the leaves should all be removed and burned, and so should whole plants when too far gone to be worthy of more attention. If the dying leaves are left to fall and drift into hot-beds, cold-frames and other places they may do much to spread a serious trouble.

Rutgers College.

Plant Notes.

Some Recent Portraits.

THE *Gardeners' Chronicle* of September 20th contains a figure of a new *Masdevallia*, for which Mr. Rolfe proposes the name of *M. fulvescens*. It is a native of New Granada, whence it has been imported by F. Horsman & Co. It is related to *M. infracta*, but surpasses that species in the brighter coloring of the perianth, which is described as "of a light buff shade, passing into light purple-brown on the constricted sides of the throat, the upper sepal deeper orange-yellow, shading into purple-brown on the two lateral nerves."

A colored portrait of a flowering branch of one of the double-flowered forms of the Japanese Cherry, *Prunus Pseudo-Cerasus*, is the principal illustration in the issue of the *Garden of London* for September 20th. It well represents one of the most beautiful flowered of all small hardy trees. A number of forms occur in cultivation, one of the most attractive being that generally known as *P. Watereri*, in which the flowers are delicately shaded with pink. The single-flowered form of this tree is much less common in cultivation than the double-flowered garden-varieties, and is less vigorous as it appears in this country and not always perfectly hardy.

A recent portrait of *Staphylea Colchica* in the Bulletin of the Royal Tuscan Society of Horticulture reminds us of the great value of this shrub as an ornamental plant. It is by far the most beautiful of all the genus, and well worth a place in the shrubbery. Moreover, it forces well, and of late years it has been very largely used in both Paris and London for supplying the winter markets with fragrant white flowers.

New or Little Known Plants.

Gerbera Jamesoni.*

THE genus *Gerbera* is composed of about twenty species, most of them natives of South Africa. The one figured on page 501 appears to be the first introduced into gardens, having flowered for the first time in the spring of last year at Kew, when it was figured and described in the *Botanical Magazine*. In habit it is quite distinct, and its flowers are so large, so attractive in color and so lasting that it is certain to become popular with cultivators. Plants of it have flowered at Kew all through the present summer and are in flower still. They are grown in pots in a cool, sunny greenhouse, and are planted in a mixture of loam, peat and sand, and kept moderately moist. Last year a plant was tried in a sunny border out-of-doors, where it grew well and flowered all through the summer and autumn. During the winter it was protected by a slight covering of coal-ashes, but, in spite of this, the frost killed it. Except, therefore, in places more favored than the neighborhood of London, this plant is not likely to prove hardy. In pots, however, it is perfectly satisfactory. Hitherto no seeds have been matured by cultivated plants, the only means of multiplying them being by dividing the woody root-stock whenever a second growth appears. The plant is described by Sir Joseph Hooker as follows:

"All parts covered with soft hairs, and the mature leaves clothed beneath with a snow-white tomentum. Leaves numerous from the perennial root-stock, petiole six to eight inches, erect; blade five to ten inches long by two to three

inches broad, runcinately pinnatifid, with the margins of the lobes undulate and cut into unequally sinuately toothed obtuse or acute lobules. Scapes ten to eighteen inches long, stout, naked. Head solitary, sub-erect, three to four inches broad across the rays. Involucre three-quarters of an inch long, campanulate, woolly, base intruded; bracts lanceolate, appressed. Flowers of the ray in one series, about thirty, narrowly ligulate, three-toothed, dull yellow beneath, bright orange or flame-colored above; . . . disc-flowers minute, of the same color as the ray-flowers."

To this it may be added that the leaves are evergreen, the flowers are rather nodding than otherwise, and they are open all day whether it be sunny or clouded. Each one lasts several weeks, and the color never loses its brightness and intensity.

This species was discovered in the Transvaal, near Barberton, now famous for its gold mines, and sent to Kew by the Curator of the Natal Botanic Gardens in 1888. Since then several other species of *Gerbera* have been procured from the same region, and these, judging from dried specimens, are likely to prove as valuable in horticulture as that here figured.

Kew.

W. Watson.

New Orchids.

MASDEVALLIA GUTTULATA, Rolfe, is an interesting little *Masdevallia* which has been in cultivation for some considerable time. The native country is unknown. It has flowered in the Glasnevin Botanic Garden and also at Kew. It belongs to the *Tovarensis* group, having triquetrous peduncles, which bear two or three flowers in succession. They are about half the size of those of *M. Tovarensis*, yellowish white in color, spotted and slightly suffused with light purple. The name is given in allusion to the numerous small spots.—*Gardeners' Chronicle*, September 6th, p. 267.

CYPRIPEDIUM × ALFRED, N. E. Br., is a hybrid raised in the collection of Mr. D. O. Drewett, of Mill-on-Tyne, from *Cypripedium venustum* fertilized with the pollen of *C. Philippinense*. It is quite intermediate in character between its parents. The scape is single flowered at present. The sepals and petals approach *C. Philippinense* in shape, while the lip is more like that of *C. venustum*. It was awarded a first-class Certificate by the Royal Horticultural Society on August 26th last.—*Gardeners' Chronicle*, August 30th, p. 252; September 13th, p. 294.

CYPRIPEDIUM × ALICE, N. E. Br., was also raised in the same collection as the preceding, from *C. Stonei*, fertilized with the pollen of *C. Spicerianum*. It strongly resembles the last named species in shape, except the lip, which is more like that of *C. Stonei*. The scape bears two flowers, which are pale and delicately colored.—*Gardeners' Chronicle*, August 30th, p. 252; September 13th, p. 294.

CYPRIPEDIUM × CONSTANCE, N. E. Br., is another hybrid raised in the same collection as the two preceding, from *C. Stonei*, fertilized from the pollen of *C. Curtisii*. It is intermediate in character between the parents, with the lip approaching *C. Stonei* in shape. The sepals are milk-white tinged and nerved with purple, and the petals pale yellowish with numerous small purple-brown spots. The scape is two-flowered.—*Gardeners' Chronicle*, August 30th, p. 252; September 13th, p. 294.

Foreign Correspondence.

London Letter.

DAHLIAS.—A great show and a special conference of Dahlias and Dahlia-growers were held at Chiswick last Tuesday. The flowers were as good, as numerous and as varied as might be expected in a country where the Dahlia has been more or less a popular garden-flower since the beginning of the present century. Mr. Shirley Hibberd opened the conference with a most interesting extempore discourse on the origin of the Florists' Dahlia. He startled the botanists by declaring that in his opinion there was no good ground for admitting more than one original species, namely, *D. variabilis*, the other five or six recognized by botanists being at most mere wild forms of that plant. Mr. Hibberd is probably right; but the same line of argument would, if followed, inevitably lead to the wholesale reduction in the number of species of tuberous Begonias, Rhododendrons, in fact of almost all genera which have discovered an extraordinary proneness to vary under cultivation. Although there is proof that the plants now known as Dahlias

*Bolus; Hook. f. *Bot. Mag.*, t. 7087.

Fig. 64.—*Gerbera Jamesoni* (reduced one-third).—See page 500.

were known to Hernandez in 1615 it was not until the year 1789 that the plant was introduced from Mexico, by means of seeds, to the Botanic Garden at Madrid. A few of these seeds were secured by Lord Bute and sent to England, where they flowered in 1790. The plants were, however, soon lost, owing to the mistaken idea that they required stove treatment. About this time this species received the name of *Dahlia coccinea*, the generic name being a compliment to the botanist, Andreas Dahl. According to Salisbury a second species, *D. variabilis*, was introduced in 1804 by Lady Holland, who sent the seeds from Madrid. Its behavior under cultivation is delightfully described by Salisbury in his paper read before the Horticultural Society in 1808 and printed in the first volume of the Transactions. The names he uses are: *D. sambucifolia* for *D. variabilis* and *D. bidentifolia* for what is now called *D. coccinea*.

The work of the florists began in 1813 in the Botanical Garden at Louvain, where a series of double-flowered forms were raised by Donkelaar. In England the Dahlia appears to have reached the height of its popularity about 1850, after which it began to decline until the founding of the Dahlia Society in 1870, which brought about a revival of the Dahlia amongst popular garden-flowers. In 1872 an additional interest and value were given to Dahlias by the introduction of *D. Juarezii*, the Cactus Dahlia. It was obtained by accident, so it is reported, from Mexico by a Dutch nurseryman, with whom it flowered in 1874. Two or three years afterward it was in the possession of the enterprising Mr. Cannell, who showed flowers of it at one of the horticultural meetings. It is probably of hybrid origin, or, at any rate, the production of the garden rather than of nature. There are now many varieties and crosses between it and the show Dahlias, but few of them, if any, surpass it either in brilliancy of color or in shape. *D. coccinea* has flowers three inches across, with a large yellow disk surrounded by a single row of scarlet, oblong ray-florets. *D. variabilis*, in some of its forms, is not unlike *D. coccinea*, but it shows considerable variety in the size and form of its flowers even in a wild state. Other species which have recently been used by breeders of Dahlias are *D. Merckii* (*D. glabrata*) and *D. gracilis*. The characters of these four are traceable in the single Dahlias of to-day.

It is recorded in the *Floricultural Cabinet* for 1858 that a figure of a distinctly double Dahlia occurs in an old work on the natural history of Mexico published at Rome in 1651. So far, however, as the double Dahlias of European gardens except *D. Juarezii* and its forms are concerned, they appear to have been first bred by Donkelaar, as above stated. The single Dahlia has only recently found favor in gardens. The sole object of the breeders of these plants in the old days was, no doubt, to get away from the single flowered varieties as far as possible. Within the last ten years or so all this has been changed, and now for every one who admires and grows the double flowered varieties there are twenty who prefer the single ones.

I have only recently noticed some of the most striking of the Dahlias grown in England at the present time. The following were awarded certificates by the Floral Committee:

- Eldorado (Show), very full, deep crimson in color.
- Othello (Pompon), a medium-sized flower, colored bright crimson.
- Mikado (Pompon), a small flowered kind, white edged with crimson.
- Comedian (Fancy), dull orange, striped and flaked with crimson and edged with purple.
- Beauty of Arundel (Cactus), crimson with maroon edges, a good, bold flower of attractive colors.
- Centennial, a large double flower, colored magenta, with deep crimson edges.
- Melita (Pompon-Cactus), small flowers, with the florets pointed as in *Juarezii*, crimson tipped with white.
- Yellow A. W. Tait (decorative), a bright, clear, yellow flower of special value as an effective border plant.
- Daisy (Pompon), yellow, with deeper shade on tips of petals.

GRAPES.—An exhibition of grapes was held at the same time with the Dahlias, and a conference of growers on the day following that given up to the Dahlia fanciers. There was a fair display of fruit, but, probably owing to the absence of a prize list, there were fewer exhibitors than might have been expected. The conference was remarkable for a paper on "The Enemies of the Vine," read by Mr. R. D. Blackmore, the eminent novelist, author of "Lorna Doone" and a market gardener besides. Mr. Blackmore deals with all the pests, insect and other, of the Vine except Phylloxera. This scourge is known to be present in more than one collection of Vines in England. So far the only really effectual remedy appears to be grafting as practiced in France, especially in Bordeaux. The stocks employed are the American Vines known as Jacquez and Herbemont and the variety *riparia* of *V. cordifolia*. Upon these the best French kinds are grafted, with, so far, perfect success—the stocks proving impervious to the attacks of the Phylloxera. A report upon this subject from Her Majesty's Consul at Bordeaux last year stated that "the regeneration of vineyards in which the European Vine had been extirpated by the Phylloxera has been effected, as was pointed out would probably be the case, by means of European Vines grafted on American stocks. Direct production from American stocks has, fortunately for the wine-consumer, been abandoned as hopeless." If the most terrible scourge that has ever attacked the Vine industry is overcome by means of grafting it ought to convince those people who declared against grafting of the absurdity of their sweeping assertion that "grafting is a delusion, a snare and a makeshift."

Papers on the subjects of "Soils and Manures for the Vine," and on "Packing Grapes," were read, the former by Mr. W. Thomson, of Cloverfords, whose work on the "Cultivation of the Vine" has done so much to make Grape-growing in England what it now is. These papers will be published in the Journal of the Society, and to any one interested in the subjects upon which they treat they may be cordially recommended as the latest utterances of the masters of the art of Grape production in England.

An Alpine Border.

IT is often difficult to find the right place in the garden for small hardy plants, odd bulbs, or pieces of things which require some special attention, or which it is desired to keep under observation. Such things planted in an ordinary border are apt to drag out a miserable existence even if they survive at all. They are usually overshadowed and starved out by their vigorous neighbors, or, if they happily secure a share of sunlight, insufficient drainage on the level is the cause of serious losses, for many of the smaller plants are especially impatient of water at the crowns. In ample grounds there is usually little difficulty in arranging a suitable rockery, where such plants may be made perfectly at home and most of the conditions for their successful culture provided. In narrower quarters, however, rockeries are seldom, if ever, satisfactory, for, while beauty must often give way to utility, it is well to avoid unsightly fixtures, and it is scarcely possible to arrange a rockery whose utility will be so great as to overbalance its incongruity in an ordinary small, flat garden. It occurred to me last spring while studying the problem of growing various alpine plants that a special border devoted to small things might be arranged which would prove satisfactory to a fair extent, and, at least, always interesting to the cultivator. Perhaps "An Attempt at an Alpine Border" would more correctly head these notes, for my planting as yet has been tentative. A long, narrow grass strip, which divided a hardy border from the main path, was turned under, and the ground was suitably prepared. On each side of this narrow border a row of stones was placed, raising it a few inches above the path and hardy border. Where any special soil is required it is supplied, and, when necessary, special elevations made or extra stones added to the soil. Plants of Arabis, Androsaces, Drabas, Aubrietias, Poppies (nudicaule), Myosotis, Anemones, etc., seem at present well established, while various labels mark where, in the spring, may be expected some of the charming visitors of the early year. It is not expected that in such a border one can grow all small alpine plants (neither can most of us manage many of them in a rockery), but this simple suggestion is, perhaps, of use to some small grower with a fancy for the dainties of the floral world, or who wishes a place that will give a hospitable welcome to odd small plants and bulbs. Such a border is inclined to dryness, no water remains long on the crowns, and, if it is not handsome, it is not obtrusive.

The loss of a turf border has caused no regret, it being always a source of care and expense and rather commonplace. Perhaps as the various creeping plants project over the edge of the walk they will agreeably break the straight line of an ugly path.

Elizabeth, N. J.

Rose Notes.

THE proper method of staking Roses which are planted out for winter blooming makes an interesting subject of study at this time of the year, when the plants are, or at least should be, in such a condition as to require some support. And careless or clumsy staking detracts greatly from the appearance of a Rose-house, besides being quite unnecessary; for neat stakes are readily procurable and at very moderate outlay. The shallow benches, so much favored for Rose-growing, do not contain a sufficient depth of soil to support the long stakes that are needed, and therefore many growers have adopted the plan of running a stout wire in line with the row of plants from one end of the bench to the other, the wire being three to three and a half feet above the soil, and the tops of the stakes are fastened to this wire. By means of this device quite slender stakes may be used—for instance, a square stake of cedar or poplar or chestnut half an inch in diameter will answer the purpose very well when supported at the top as described.

This makes quite a neat arrangement; but a less conspicuous one for the same purpose is composed entirely of wires, by using parallel upper and lower wires and replacing the stakes with upright wires fastened to each of the horizontal ones. The latter method offers the least possible obstruction to the light and also to the force of water when syringing, and provides a strong and durable trellis.

Another method of supporting Roses was recently suggested by a practical grower—namely, to stretch strips of wire netting above the bench and supported by a vertical wire at each side of the bench. The shoots of the Roses are to be tied to the netting, and it is expected that the plants will thus be spread out more, and, in consequence, receive more light and air than when tied in the usual manner. The netting alluded to was that made from galvanized wire, and of large mesh.

The often repeated injunction that Roses require plenty of fresh air should be well observed at this time of the year, so that all the growth the plants make is firm and solid, and, therefore, fit to withstand the strain of continued winter flowering. At the same time strong draughts should at all times be avoided, as mildew is sure to follow. A little artificial heat is generally found necessary at night in this latitude by the 1st of October, but this must be regulated by the weather, and some seasons it may be needed before this time; but the firing should be regulated carefully, for too much heat will do quite as much harm as too little. At this season of the year the advantages of steam heating for certain purposes become apparent, as the temperature may be more easily regulated under this system than with hot water, and this is nowhere more noticeable than in the Rose-houses.

Black mildew, or "black spot," as it is generally known, is now appearing on those varieties for which it shows a special preference, and may be increased rapidly by one over-watering, and this makes it essential that the watering should be done with caution at all times. A reliable remedy for this much-dreaded Fungus would be a great boon to Rose-growers, but thus far a real specific has not been discovered, though many have been tried. The most effective treatment seems to be the picking off of the affected leaves and the removal of all decayed leaves from the surface of the soil. This does not cure infected plants, but it helps to check the spread of the Fungus to a certain extent.

In the matter of varieties there seems to be but little change among commercial growers this season, most of the sorts favored last year remaining standard for this winter's trade. Among the newer varieties, Duchess of Albany and Madame Hoste are far in the lead in popularity, and both of these excellent sorts have been largely planted. Pierre Guillot finds favor with some large growers, though this Rose does not seem to grow freely in all soils. The flowers keep well after being cut, however, and when well grown have a fine color.

The general verdict seems to be that W. F. Bennett, though a beautiful flower when in good condition, does not pay the grower because it shows too many short-stemmed flowers, which do not sell well, and though there are many small lots of this variety to be seen, yet a hundred-foot bench of it is now a comparative rarity. Souvenir of Wootton does not seem to have superseded American Beauty, as was hoped at the time of its introduction, but still it is reported in some

instances to have proved a profitable variety last winter, and it will probably continue to be prized—at least for the local trade.

Holmesburg, Pa.

W. H. Taplin.

Notes on Shrubs.

Stephanandra flexuosa, first introduced by Veitch & Sons from Japan, has matured a little fruit at the Arboretum this season, the seed ripening in the latter part of September. Comparatively few of the numerous small blossoms which the plant bears develop into fruit, and a large proportion of this is without good seed. However, seed may be produced more freely as the plants become older. The fruit resembles that of the closely related Nine-Bark (*Physocarpus opulifolius*), except that it is a very great deal smaller. Usually only one, or rarely two, seeds are borne in a pod.

The little white flowers which this plant produces in June are not individually showy, but in the middle of the month, when

September, and it remains on the plants and keeps its brightness for a month or more. The pods are unusually large, and are produced in flattish clusters of from six to ten or more, suspended on slender stalks two or three inches in length. They are of a deep pinkish red color, and with the bright scarlet arils, which they disclose upon opening, they make a very handsome appearance; and as the long peduncles allow the clusters to hang much below the branches and foliage they make an effective and little obscured display of color.

E. latifolia is rarely seen in cultivation here, and when found in gardens usually presents a poor appearance by being stunted and crowded by other trees and shrubs. Under favorable circumstances it may attain a height of from ten to twenty feet. The leaves are large and broad, smooth and almost shining. The branches are smooth, the young shoots being reddish green in winter; and in the long, tapering, pointed, green buds we have a character which assists us in determining this species from all others when they are destitute of

Jeannette Park, New York.—See page 498.

they are most abundant, they present a delicate, graceful appearance, mingled with the fine foliage. It is for the sake of the foliage quite as much as for the flowers that this *Stephanandra* is of interest and value for ornamental purposes. The deeply cut and serrated, triangular, pointed leaves are about an inch in length; they are of a dark green color, and are sufficiently abundant to effectually cover the branches and stems. This is a fast-growing shrub, and while it has a somewhat close and bushy habit, it maintains a light and graceful appearance not possessed by many hardy, woody plants.

Although it has not been sufficiently well tested to warrant the statement that it is hardy, it at least promises to be an interesting and valuable addition to the list of plants which will do well in sheltered situations in this latitude.

While the fruits of nearly all the species of Spindle-trees (*Euonymus*) are more or less showy when they reach maturity, there are few which, for beautiful and showy qualities, produce fruit equaling that of the Broad-Leaved Spindle-tree (*Euonymus latifolia*) in its best condition. The fruit is perfected comparatively early in the season, being fully ripe early in

flowers, fruit or foliage. In common with nearly all plants, the various species of *Euonymus* show great differences in the times of maturing of fruits, and even in different plants of the same species there is sometimes as great a variation as a month in the opening of the pods. The common European Spindle-tree (*E. Europæa*) sometimes shows this in a very marked degree; and so does the Japanese Winged *Euonymus* (*E. alata*), so called because of the thin, corky excrescences on the branches, which give them a four-angled appearance. These thin excrescences or plates are produced at right angles to each other in the lines of the buds and branchlets which break their continuity at regular intervals. In some plants the corky excrescences are not very prominent, in others they are often a sixth of an inch long. The fruit of this species is small and mostly contains only one developed ovule, and as the stalks are short the pods appear almost sessile on the branches. On different plants the period of ripening or opening of the pods extends from about the 10th of September until near the end of the month or later. Although the arils of this species are of as bright a scarlet color as any in

the genus, they are not nearly so showy because they are small and much hidden by the leaves. The foliage of *E. alata* assumes rich purple, rosy red or scarlet colors in the autumn, constituting its chief merit and value in ornamental planting. A less valuable plant is the Warty-barked Euonymus (*E. verrucosa*) of central Europe. It is a species of close, upright habit, and with light green leaves. But neither foliage, flowers nor fruit are particularly striking; the chief interest and peculiarity being in the little wart-like excrescences by which the bark is thickly covered.

Arnold Arboretum.

J. G. J.

Growing Hippeastrums.

ONE of the most interesting papers in the latest volume of the Journal of the Royal Horticultural Society is on the Hippeastrum, or, as it is more generally known in gardens, the Amaryllis, by Mr. Harry Veitch. The story of the development of these flowers by selection and crossing up to their present beauty of form and varied brilliancy of color is admirably told, but we have space only for the following paragraphs relating to the cultivation of these plants.

SOIL.—The compost should consist of two-thirds good fibrous loam, such as is used for vines, and one-third cow manure fresh from the stall. These ingredients should be brought together toward the end of July, and allowed to remain in heap for about three months, when they should be turned over and well mixed together. The mixture must at no time be allowed to get too wet, and when required for potting, in the early part of the following year, a proportion to the whole of nearly one-third of silver sand should be added.

POTTING.—The pots selected should be in proportion to the size of the bulbs, and the smaller the pots that can be so used the better; in every case the drainage must be ample. Before potting, every vestige of old soil should be shaken off, and any decaying roots, and any other decayed matter that may be found about the bulbs, should be removed. The potting should be performed according to the time the bulbs are required to be in bloom, a period of eight to ten weeks being the usual interval between the potting and the flowering of the bulbs. We usually commence potting about the middle of January, and have bulbs in flower about the middle of March, the flowering season continuing for eight to ten weeks. After potting, the pots should be plunged in some suitable material; no bottom heat should be applied at first, but the bulbs should be allowed to start into growth as gently as possible.

TEMPERATURE.—After potting, the temperature of the house should be maintained at fifty-five degrees for three or four weeks, then a little bottom heat should be given, and the temperature of the house raised to sixty degrees F. With this temperature the house should be damped down occasionally, and when the weather is warm and bright a little air should be admitted at the top for a couple of hours in the middle of the day. When in flower, a light shading should be used to prolong the flowering season.

WATERING.—This requires the most careful attention; it is, in fact, the pivot on which successful Hippeastrum culture turns. More bulbs are injured or die from excess of water than from any other cause, and excess of water is one of the causes of the so-called Eucharis mite, one of the most destructive pests the cultivator of the Hippeastrum has to contend with. At the time of potting, the new soil should be a little moist; after potting, no water should be given for four or five weeks, or till the foliage and flower-scapes have attained a height of two or three inches; then it should be sparingly applied until the flower-buds appear, but from that time a more liberal supply should be given till the foliage is perfected; it should be then gradually reduced until about the middle of August, when it should be withheld altogether. Eight or nine weeks later the pots may be lifted out of the plunging material, and after an interval of another month all the plunging material should be removed from the house and the bulbs kept perfectly dormant on the stage till the potting season comes round again; the house, too, should be kept as dry as possible the whole time the bulbs are at rest. We use no liquid or artificial manure at any time. Much has been written in the horticultural press about the mite that appears both on the Eucharis and on the Hippeastrum, but we have no fear of it. In my opinion its prevention is simply a matter of not over-potting and not over-watering, and we have seldom seen bulbs, however badly affected, that could not be brought into perfect health again.

TREATMENT AFTER FLOWERING.—After flowering the pots should be kept plunged, and each pot and about half the exposed part of the bulb should be covered with the plunging material. When the roots begin to push, more bottom heat and more water should be given; the atmosphere of the house should be kept more humid, and the foliage occasionally syringed. In bright, warm weather a slight shading should be used, and the growth of the plants encouraged to proceed as rapidly as possible; for the stronger the bulbs the finer will be the flower-scapes and their flowers in the following spring. Toward the end of July the bulbs should be gradually ripened by diminishing the shading, and three or four weeks later the shading may be discontinued altogether and as much light and air admitted into the house as possible.

INSECTS.—There will be no difficulty with these pests if their first appearance is watched for, and their increase checked as soon as they are discovered. Thrips will spot the foliage, but fumigating occasionally will keep them under. During the summer months red spider will also attack the foliage, but their increase can be prevented by syringing and by keeping a moist atmosphere in the house. Sometimes mealy-bug appears, especially if the bulbs are placed near plants subject to the attacks of that plague; but it can be easily kept in check by cleaning or syringing with blight composition once or twice a week, and in winter, when the foliage has fallen, it can be seen and removed without much trouble.

Some cultivators of the Hippeastrum, as Mr. R. S. Holford, of Westonbirt, who possesses the finest amateur collection in this country, do not report their bulbs annually, nor do they plunge them as we recommend, but give them liquid manure during the growing season. The bulbs are also grown in different houses amongst other plants, and in vineries, and most successfully, too, with the advantage of prolonging the season to such an extent that a Hippeastrum in flower can usually be seen at any time of the year. The value of the Hippeastrum as a decorative plant can thence be scarcely underrated, for even when the scape is cut and placed in water the flowers continue fresh nearly as long as if left on the bulb. Some of the Dutch growers treat the Hippeastrum much in the manner we do, notably Mr. De Graaf, of Leyden, whose collection is a magnificent one, and to whom we are indebted for very valuable information when we commenced the cultivation of this beautiful plant, and with whom we are now in friendly rivalry in the raising of improved forms.

Achillea serrata, fl. pl.—My former note in GARDEN AND FOREST (p. 408) on the merits of this plant has called forth many inquiries, and I notice in the last number Mr. E. S. Miller's method of increasing it. A strong clump of this Achillea will produce quite fifty stolons, and if the plant is placed in a cellar until January each of these stolons will, if used entire when potted up, make vigorous plants with as many as six leading growths, and I consider this the best plan to adopt where a limited number of good plants are required. For trade purposes, where it is desirable to get the largest number from a given quantity of roots, it certainly is possible to take cuttings from every joint of the stolon, but, except for trade requirements, the plants will not bear comparison with those obtained from the use of the entire stolon potted in January or February. Achilleas may also be easily propagated from the young shoots produced on the flower-stems after the flowers are past, and if wintered in pots make good plants the next year.

Anemone Japonica.—The pot-culture of this Anemone, as advocated by T. D. H., is certainly a good way to treat this most delicately beautiful of autumn flowers. It was my privilege to see the plants spoken of, and better examples of good cultivation could not be desired. When I saw them they were already in flower, while ours in the same district, but planted out, were fully two weeks later. This season's frost did not visit us until the last week in September, and the Anemones have had ample time to flower and make a nice display, but when they can be had two weeks in advance by pot-culture this alone in some seasons would warrant the adoption of this method. Pot-plants of Anemone grown in this way are most serviceable for house-decoration, and help to fill the gap which always occurs between the loss of outdoor flowers and the advent of the Chrysanthemum season. If all roots of Anemones that are as thick as a Wheat straw are lifted in fall and placed in the cutting-bench they will at once begin to grow and may be potted in three-inch pots, and if these are grown on into ten-inch pots, and plunged out-of-doors in May, fine flowering specimens will be produced in September. In more favored sections the same pot-raised plants may be planted out-of-doors, there to remain, but in

the northern states this Japan Anemone is not reliably hardy, and it is always best to lift the roots and store them in a cool cellar until spring.

South Lancaster, Mass.

E. O. Orpet.

Vallota purpurea.—The Scarborough Lily (a name under which this plant was more generally known in England some years ago than it is at present) is one of those plants a well-grown specimen of which at once commands attention. The genus, named after the French botanist, Pierre Valot, has this representative alone, and it belongs to the *Amaryllidaceæ*. The Vallota was introduced from the Cape of Good Hope in 1774. The bulb is large and firm; leaves strap-shaped and evergreen; scape slightly longer than the leaves, bearing from five to ten, and sometimes even more, bright scarlet, funnel-shaped flowers in the form of an umbel. The plant succeeds best in the greenhouse, and it is an excellent subject for cultivation in the dwelling-house. It is rather a common plant in gardens, but from the weakly specimens generally seen it is evident that its cultivation is far from being perfectly understood. The soil best suited to its requirements is a mixture of good loam, fibrous peat, thoroughly decomposed farm-yard manure and sand in equal parts. When potting is necessary, it is best done soon after the flowering season. Care should be taken that the bulbs are disturbed as little as possible, and their crowns should be on a level with the surface of the soil. Frequent or annual potting is injurious, and should only be undertaken when a shift or renewal of soil is absolutely necessary. In the meantime give plenty of water and stimulating liquids during the season of growth. It is a mistake to dry off the plant periodically, for it needs no season of perfect rest like most other bulbous plants. In its natural state it is found in marshy districts, and it practically knows no dry season. Of course less water will supply its needs in winter, but at no time should the soil be allowed to get dust dry. The pots may be set out-doors during the summer months with advantage. In such cases a bright, sunny position should be chosen, with an ample supply of water, and the roots protected from the burning sun by shading the pots. The flowering season lasts through August and September, but if the plants are strong and healthy this season may be hastened or delayed by several weeks. The stock may be readily increased from the offsets which are freely produced by vigorous plants. There are several varieties of *Vallota purpurea*. Some of these have larger flowers than the type, in others the flowers are a trifle brighter.

Botanic Gardens, Cambridge, Mass.

M. Barker.

Spraying against Pear Blight.—The orchard of Mr. J. M. White, of Middlesex, New Jersey, contains some 1,200 trees, and early in the season the spraying was begun with a Nixon cart-pump, throwing two strong streams. With this cart and three men, with a boy to lead the horse, the entire orchard was sprayed thoroughly in four hours. The first spraying was with a mixture of London Purple for insects, and carbonate of copper with ammonia for the Blight Fungus. One Clairgeau tree was left unsprayed, and from this the leaves fell very early and the few pears produced soon followed. They were small, blotched and cracked so much as to be about worthless. The surrounding trees of the same variety retained their foliage well, and, as this was an off-year, prices were high and profits great. Mr. White saved several hundred dollars on his Clairgeau pears alone. The Duchess and other varieties were also benefited, as may be inferred from the fact that their owner secured an unbroken list of first premiums at the State Fair. This case is simply cited to show that the time has come when spraying machines of some kind must be adopted as regular implements on the farm. It should be understood that they can be used for the potato-field as well as the orchard and vineyard.

The Forest.

The Forestry Exhibit at the Columbian Exposition.

WE find in the *Southern Lumberman* a paper read by Mr. Henry L. Tolman at the meeting of the Lumber and Forestry Committee of the National Commission in charge of the coming World's Fair at Chicago. The extracts given below will furnish a good idea of the character and scope of such an exhibit as the enlightened lumbermen of the country think the forest-interests of the country deserve:

The lumber business ranks third in commercial importance among our domestic industries, and for several reasons is en-

titled to a prominent department in the Columbian Exposition. The products of our forests are so varied, the forms into which they are manufactured so numerous, and the multitude of wood-working machines so great, as of themselves, when properly classified and arranged, to make a large and attractive display, not only to those directly interested, but to the world at large.

Again there is a scientific department to which attention has never been called, but which, if properly developed, would be of rare and novel interest. A study of the cell structure of trees in health and disease furnishes the only means for answering many of the practical questions—as to why wood decays, the relative value of sap and heart wood, butt or top logs, the comparative worth of Wisconsin, Kentucky or Louisiana white oak, white or yellow pine, white and red cypress, the comparative value of cedar, poplar, cypress, redwood, fir and other woods. Physical tests for transverse strain and compression made by elaborate and costly machines are constantly necessary to determine similar questions as to breaking weight, and their results can be instructively and effectively shown. A vast belt of Short-leaf Yellow Pine extending from Maryland south, skirting the Blue Ridge Mountains their entire length, and fringing the northern edge of the great Long-leaf Pine belt as far as central Texas, is rapidly coming into market, but the prejudice against it has been so great that until the last two or three years it has been compelled to masquerade under another name to find purchasers. Its inferiority has been greatly exaggerated, and science only can best determine its value as compared with that of its better known rival, the so-called Georgia Pine. The Government has recently begun measures to recover damages from turpentine distillers who have been boxing trees on unsold lands without license, on the ground that such boxing injures their growth and deteriorates them in value, and science will be called on to answer this question.

Extensive forests of Sweet Gum fill the swamps of Georgia, Alabama, Mississippi and Louisiana, which are comparatively valueless, because no successful way has been found of drying the lumber without serious surface checking, and science must solve the difficulty. Scientific facts are disseminated very slowly among the people by the ordinary channels, and the occasion we propose to celebrate offers an opportunity unequaled in the history of our country.

Having thus very briefly outlined a few of the many ways in which the solution of these scientific questions can be of real practical advantage, permit me to suggest how such an exhibit should be made.

First, there should be specimens of all the four hundred and twenty-five species of trees with which nature has beautified this, the forest continent of the world. These specimens should be cut at least three feet long, flat and rift sawed, so as to show grain and pattern, and giving bark, sap and heart wood. All boards should be dressed, and some of them polished in different ways to show the best manner of treating them. Transverse sections of the butt and top cuts should also be obtained, at least of the commercially valuable woods, to show the annual growth of rings, thickness of sap and bark, etc. If possible, specimens of leaves, flowers and fruit should likewise be obtained, not only for the aid of professed botanists, but to enable lumbermen to identify species, as it is a well known fact that common names of trees vary greatly according to the locality. In the Oaks, especially, the confusion of names is very annoying, and the quality of the different species varies greatly. Another interesting feature would be photographs enlarged under the microscope of specimens of woods, which would show far better than any ordinary examination the causes of the difference between different species. Numerous and exhaustive physical tests, such as were made of the various woods under the direction of the Census Bureau in 1880, should be shown, the results of which afforded valuable evidence as to the relative resistance of the various woods to strains and compressions, and their adaptability for bridge building, railroad ties or sills, and the like, or, on the other hand, for furniture or interior decoration. No wood unites in itself all the desirable qualities, and as gradually one after another of the most valuable kinds of wood become exhausted, at least in merchantable quantities, greater attention must be paid to the selection of satisfactory substitutes.

Besides specimens of native forest-grown trees, there should also be others of trees artificially planted in various sections. Some of them are large enough to give valuable data as to the comparative growth and quality of naturally-grown and planted-out trees. The same work might profitably be pushed still further, and important data thus be obtained toward

settling the vexed question as to whether our native forests can be replaced by artificial planting. The booths or rooms in which such exhibit is made should be constructed of native wood entirely, arranged so as to make practical application of the scientific facts above mentioned, and this feature would offer an indefinite field for expansion, where rival states as well as lumbermen could display their products.

Closely connected with this scientific portion, so as to show it to be a part of one symmetrical whole, should come the wood-working machinery of every kind, beginning with some specimen of the primitive sash or pit saw, through the wide range of circular and band saws, then gang saws, edgers and trimmers, shingle and lathe machines. Practical examples of the operation of this machinery should by all means be given, either on certain days or at certain hours. After these machines designed for reducing the raw material to manufactured form would naturally follow the more intricate planing machines, tenon and mortise machines, surfacers, moulding, barrel, matching, veneer, pail, nailing, sand-papering and turning machines, and the wonderful and novel carving machines, where the numerous manufacturers would properly have all the needed space to show the advantages of their rival inventions.

Lastly, it would be eminently proper, though perhaps not practical to the full extent, to have connected with the lumber and forestry exhibit a display of all kinds of articles made of wood, carved specimens, wood pulp, and the numerous articles made from it, such as pails, dishes, pressed ornaments, etc.

Too much stress cannot be laid on the necessity of system in such a varied and extended exhibit. Though logically the parts are all intimately connected, yet a careless, immethodical display, difficult to comprehend, would leave the ordinary visitor with no definite notion of any part, while one strictly subordinated to an orderly progression would give a clear, though perhaps from the nature of the case often a superficial view, but one which could easily be remembered and of permanent benefit.

Of equal importance is the question of some government supervision of at least the scientific part of the exhibit, if it can be done within the limits of the act. Lumbermen and machinery makers, practically interested, can be trusted to make a fitting display in the direction in which they are acquainted. They represent a broad minded class of men, already greatly interested in the widest success of a lumber exhibit, who can be relied on to join heartily in the exhibit, if only a proper initial movement is made. Hence the necessity of a generalship declared by a higher authority, not only impartial, but more catholic.

The best interests of the lumber industry, as well as of the Exposition, will be subserved by an exhibit covering as near as possible all branches of this department and allowing no one to usurp undue importance.

Correspondence.

Improper Pruning.

To the Editor of GARDEN AND FOREST:

Sir.—Will you give us your views on the removal of the lower branches from ornamental trees? Many people here insist that all lower branches must be trimmed away in order that the ground may be thoroughly cultivated up to the very trunks of the trees. Clumps of conifers, Grevilleas, Acacias and other trees are spoiled in this way and have about as much beauty as an ostrich. I leave you to imagine what an *Araucaria excelsa* looks like treated in this way.

Santa Barbara, Cal.

F. D. O.

[It should be the aim of cultivators of ornamental trees to preserve as far as possible all their lower branches. The highest type of beauty in a lawn or park tree is that in which the lower branches repose on the ground, and which present a solid mass of foliage from top to bottom. It is not easy always to produce trees of this description, and it can only be accomplished by allowing them abundant room and air on all sides for free growth and development. Even with sufficient space about them, certain trees, like some of the Pines and the Sugar Maple, lose their lower branches early and develop tall naked trunks. Lower branches are essential to the beauty of all coniferous trees which grow naturally with a pyramidal habit, like the Firs, Spruces and Araucarias. Nothing is more ugly than one of these trees deprived of its lower branches growing by itself as a specimen.

Lower branches perform a valuable service to the tree, especially such trees as grow in very moist climates or in situations where they are exposed to high wind. Young trees, like Firs and Spruces, which grow generally on high mountains where the rainfall and wind are excessive, are provided invariably with long lower branches, which have two purposes: first, to check evaporation from the ground immediately about the stems of the trees, and then by keeping the principal weight of the branches near the base of the tree to enable it to withstand severe lateral pressure from wind. Such trees as they grow naturally in the forest become crowded, and the lower branches being deprived of light, cease growing and gradually die and fall off, being no longer needed for the welfare of the tree, which is protected by its neighbors from evaporation from the surface of the soil and from the sweep of the wind.

A specimen tree growing by itself with all its lower branches preserved is in very much the same condition, so far as protection is concerned, as the same tree growing in the midst of a dense forest and entirely destitute of branches for a height perhaps of fifty or sixty feet. That this is true appears from the fact that if all its neighbors are cut away from about a tree which has grown in a dense forest, it will soon perish from exposure to the sun, or will succumb to the first severe gale. It is more important to check evaporation from the surface immediately about the trunk of a tree than it is to cultivate the ground. Trees feed only through the ends of their roots, which extend laterally as far or further from the trunk than the branches. The place to cultivate a tree is outside the spread of the branches, and not beneath them. The removal, therefore, of the lower branches of ornamental trees, especially of conifers, is a barbarous practice, which destroys their beauty and sometimes seriously threatens their existence.—Ed.]

Forest Destruction.

To the Editor of GARDEN AND FOREST:

Sir.—The impassioned oration of Mr. O'Neil, which is reported in the letter from Tupper Lake Station in the New York *Tribune* of October 6th, contains some extremely careless talk. How can a man expect what he says to be taken seriously when he declares that "there is no danger that the Adirondack forest will ever be destroyed"? Anybody who has any considerable knowledge of the region knows that great areas of it have already been entirely and finally destroyed. Every traveler from this Deadwater region down through the "Schroon country" to North Creek sees all day a scene of utter desolation unrolled before and around him. Not only has the forest been destroyed. That in itself would be but a slight matter, though every tree and bush and twig had been removed. But on these hills, across leagues and leagues of country, the soil itself has been destroyed and removed, and the rocks lie bare and glistening to the sun. This soil was the accumulation of countless ages of vegetable growth, and its destruction brings back the conditions under which nature began the work of placing it here. Everybody but Mr. O'Neil is aware that this region, now so utterly ruined, was formerly covered by most valuable forests. Now it will require uncounted centuries to clothe these bare rocks with the soil required to sustain a forest again. He says that traces of abandoned farms are to be found in all parts of the region. That is very true. But he says the owners have fled. Yes, they have fled to the adjoining tracts. Each one, after he has burned out and exhausted the soil of the acres he cultivated till it will never produce trees again, has moved a little farther up or down the valley, or over to the opposite side of the stream running through it, there to repeat the same process of devastation, not of the forest only, but of the soil itself. But the ruin of the aggregate area of their "farms" is a trivial matter compared with the destruction which has been produced by the extensive forest-fires which these farmers have recklessly started in burning off the brush and timber in order to plant a crop in the ashes. These people are still "fleeing" from place to place within the Adirondack region, and burning out new farms, which will in turn soon be abandoned.

It is no wonder that people who are familiar with the country along the Chateaugay Railroad should regard with apprehension the extension of the Northern road to Tupper Lake,

and the establishment of charcoal kilns along its line. The best basis for work for improvement is usually the recognition of existing conditions and facts.

Deadwater, N. Y.

R. D. W.

Spring or Fall Planting?

To the Editor of GARDEN AND FOREST:

Sir.—There are some things that it seems are never settled. The reason is, that their settlement depends on conditions which may vary in every individual case. One of these things that are destined to remain in dispute is the question of spring or fall planting. I have always contended, with the best authorities, I believe, that trees may be planted at any season of the year, provided it be done with proper care. The question then remains, what is "proper care"? and the kind and amount of care necessarily differs with the season and locality.

I wish to call attention to one care which may be necessary where fall-planting is practiced in northern latitudes, and which suggested itself to me when inspecting the plantations of M. Joly, near Quebec, after the meeting of the American Forestry Association at that city.

M. Joly de Lotbinière, whom all defenders of the forest know, or ought to know, as one of their staunchest and most influential friends in Canada, delights in making the Black Walnut grow far beyond the natural limits of its northern distribution. As recorded at length in the Proceedings of the Forestry Congress for 1885, after the severe winter of 1884-5, quite a large number of his trees were found dead in the spring. Examination developed the fact that the bark had been severed from the wood below the root-collar underneath the ground and for some distance along the roots near the surface of the soil; it was also observed that the trees which had succumbed stood in places where the wind had been able to sweep away the snow. The soil had evidently been severely frozen, and when thawing, in contracting away from the roots, had torn off the bark; where the frost did not penetrate the roots remained intact. M. Joly now has provided Willow hedges to collect and hold the snow, or he packs it where it seems necessary.

This suggests that where the soil has been newly dug the danger from frost is very great, since seedlings are sometimes entirely uprooted and heaved out by the frost; and that snow is a very efficient mulch where mulching is one of the cares which may be necessary for fall-planting in cold latitudes.

By the way, it seems to be time that a forestry association should avoid such planting as was performed at the end of the meeting at Quebec, where two Hickories sent from the sunny clime of Tennessee—from Andrew Jackson's own grove, it is true—were set out on the cold rock in front of the Parliament Buildings. Though the sentiment was praiseworthy, sound forestry would forbid the use of such plant material, which is bound to succumb, and the Forestry Association cannot afford to set so bad an example.

Recent Publications.

The Flora of the Kurile Islands, by K. Miyabe. Memoirs of the Boston Society of Natural History, volume iv., No. 7. Boston, 1890.

This excellent piece of work is from the pen of a former student in Harvard University and now the professor of botany in the college at Sapparo. After some general remarks on the physical geography of the Kurile Islands and a carefully worked out analysis of the composition of the flora, Mr. Miyabe gives a catalogue of the 307 species of plants which have been detected on them at different times, including those noticed by himself during a journey made to some of the southern islands in 1884. The critical notes on the characters and distribution of many of the species are specially valuable and interesting, the whole forming the only account of the flora of this group of islands, which extends for a distance of nearly 800 miles, from the Island of Jesso to the southern point of Kamschatka, and forms the boundary between the Sea of Okhotsk and the northern Pacific. Only a few of these islands are inhabited, owing to their barrenness and lack of good drinking water, and all are precipitous and inaccessible from the south side. The few bays which they do possess on the north-west and north-east sides are barely protected from the wind and do not serve as safe harbors for vessels. It is not remarkable, therefore, that so little has been known of their natural history, especially as they are encased in ice from November until April, while navigation in their

neighborhood during the early summer months is made difficult and dangerous by drifting ice from the north.

Mr. Miyabe's analyses of the composition of the flora bring out the fact that 84 per cent. or 156 of the genera of plants found on these islands occur in Europe, northern Asia and North America; while of the remaining thirty-one genera only three, *Skimmia*, *Crawfordia* and *Acanthopanax*, are confined to eastern and tropical Asia, while there are only four genera in the Kurile Islands which are peculiar to eastern North America and to eastern Asia—these are *Leucothoe*, *Diervilla*, *Hydrangea* and *Astilbe*. When it comes to species, thirty per cent. are distributed through Europe, northern Asia and North America, while only two rather doubtfully endemic have been noticed on the islands, whose flora is also remarkable in view of their northern position in the small proportion of circumpolar species. Fifty-five species extend into Europe, while eighty grow in North America. Of these, thirty-four are limited to north-western America, including Alaska and British Columbia; twenty-two extend southward to the Rocky Mountains and through the high mountain ranges of the Pacific states, and twenty-four are widely distributed across the continent.

Mr. Miyabe's conclusions, based on a careful investigation of this insular flora and of its relations to the floras of America and north-eastern Asia and of Japan, lead him to agree with Professor Milne in the opinion "that at the time of the last great southerly migration of the rich polar flora, Japan received her portion mostly through the Island of Saghalin, and but little, if any, through the then incomplete chain of the Kurile Islands."

The report made by the Earl of Meath on the public parks of America to the Committee of the London Council on Parks and Open Spaces has now been printed, by order of that body, in pamphlet form. It contains Lord Meath's views upon the American park system, already expressed in an article published in the *New Review* for May, and noticed at the time in this journal. The descriptive list of parks and open spaces in America, which is appended to the report, contains more complete statistical information of the area, cost, etc., of the pleasure-grounds of the United States than will be found elsewhere.

It appears from this report that of the large cities of the world of which we have park statistics, Paris is the best provided with parks with 25.55 acres for every 1,000 inhabitants, and a total park acreage of 58,000 acres. Vienna comes next with 7.25 acres for every 1,000 inhabitants and 8,000 acres of park. The park capacity of Tokio surpasses that of other European cities and of all the large American cities with 6 acres for every 1,000 inhabitants and 6,000 acres of park. London, with 22,000 acres, has but 5.76 acres for every 1,000 inhabitants, while New York, with the new system of parks included, has but 4.29 acres for every 1,000 inhabitants. Philadelphia has but 3.38 for every 1,000 inhabitants, while Chicago, which is better provided with parks than any other large American city, has 5.66 acres for every 1,000 inhabitants.

Lord Meath finds several things to admire in the American parks, and names, especially, the introduction of tropical Water Lilies into fountain basins in the parks of Chicago and New York, the lofty Palm-houses in South Park, Chicago, and in Druid Hill Park, Baltimore; the public ball-room in Jackson Park, Chicago, a permanent structure of stone and brick sufficiently large to contain 2,500 people, with a floor of polished maple for dancing and a music gallery; the lawns in Central Park in this city and in Prospect Park in Brooklyn, specially devoted to such games as tennis, croquet, base-ball and archery; the setting aside of special places for picnics, a custom which prevails in all the large parks of this country; the boats and carriages owned and controlled by the commissioners of some of the parks and leased to visitors for a fixed price; the swings which are provided in Central Park for children, with goat-carriages, swan-boats and other devices for their amusement; the music, which is provided free in almost all the principal parks of America, and especially the open-air gymnasium, one of the features of the Charles River Embankment in Boston. The lighting of small parks and other open spaces in American cities Lord Meath finds worthy of imitation in London, and it is surprising that in a city so crowded the open spaces have not already been made available for the public during the night in this way.

Notes.

At Indianapolis, Dr. Britton, of Columbia College, read a paper, prepared by request, which gave an account of the present state of systematic botany in North America.

Cyclamens are largely grown in Berlin, and at a recent flower show in that city there were forty exhibitors of this plant.

Plants one year from seed are strong, and bear from fifty to a hundred buds.

Sir Joseph Hooker's interesting and sympathetic account of the scientific career of the late John Ball prepared for the Journal of the Royal Geographical Society has now been issued separately.

In an article on irrigation in China, General Tchong Ki Tong says in the *Revue Scientifique* that the system of water regulation in that empire is one of the greatest achievements of the intelligence and labor of man.

Very striking just now, when flowers are rare, are tall plants of Maximilian's Sunflower. In good soil these are eight or ten feet high, and where they have been properly tied up they spread out into a great dome of bright yellow blossoms which last a long time.

One hundred and sixty-five varieties of Rice, says a recent writer in the *Popular Science Monthly*, are recognized by the planters of Ceylon. The product of Chinese plantations was greatly improved by the influence of imperial edicts prohibiting the planting of any but the largest grains, while the best variety grown in our own country is due to the intelligence of a South Carolina planter who, noticing some very long grains on an ear, secured them and perpetuated their excellence.

Mr. E. W. Hammond, of Wimer, Oregon, sends the dimensions of an Elder-tree (*Sambuca glauca*) growing in Jacksonville, the county-seat of Jackson County, in that state, which are worth putting on record. This remarkable specimen, which is believed to have been planted in 1859 or 1860, now girths seven feet two inches at three feet from the ground. The trunk retains the same size up to five feet; then increases somewhat up to its division into main branches, which occurs at eight feet from the ground. The spread of the branches is thirty-three feet, and the total height of the tree about forty. The enlarged base of the trunk girths 141 inches.

Mr. Charles Mohr has published an interesting pamphlet on "The Medicinal Plants of Alabama," describing not only their distribution and their characteristics, but the proper time for collecting their useful portions. As the forests north of the Ohio have been cut away, the centre for the supply of medicinal plants has shifted to North Carolina and the northern parts of Alabama are now also being drawn upon. Most of these plants are forest-nurslings, and thus, says Dr. Mohr, "we find the interests of the healing art closely connected with the question of the preservation of the forests of our country, and the pharmacist should feel in duty bound to unite his efforts with those who are already striving to secure this important object."

A method of marketing fruit which originated in Schleswig, but which has extended to many other parts of Germany, has proved successful in securing buyers against a bad article and in giving an opportunity for good growers to make sales of a good article. Samples of various fruits are placed in dishes for exhibition in a sales-room by growers who are prepared to furnish various kinds. The buyer has only to write his name and address on a card, with the quantity he wishes, and leave it at the central office, with the number of the plate. The order is then forwarded from the office to the grower, who in turn delivers his goods there. Here the fruit is inspected, and if it comes up to the sample in quality it is forwarded to the buyer. If it proves inferior it is returned at once to the grower. A grower who, on three occasions, furnishes goods inferior to the samples is excluded from the market. The office receives 10 per cent. commission for inspecting, forwarding, etc.

The *Gardeners' Chronicle* says that a technical school has been established at Lambeth for the purpose of teaching weaving on the most scientific principles, and also for that of testing the leaves of all promising plants, "to see if any suitable substitutes for Flax and Hemp can be discovered. Previous would-be discoverers . . . have failed through want of funds, time, patience or some other necessary. At the factory we now speak of the leaves of Agaves, Aloes, *Phormium tenax*, Palms and Rhea have been tried with good, but not entirely satisfactory, results. The processes necessary for the conversion of a fibrous leaf into a textile fabric are complex and tedious: among many others may be cited those of removing the gum, combing, spinning, bleaching, dyeing and weaving, which not only have to be performed, but done as well and speedily as possible. To find any plant with fibre which will lend itself to all these processes and which will be sufficiently cheap and productive is the aim and the object of Mr. Taylor Burrows, the manager of the factory, who is prepared

to test any fibrous plants submitted to him for that purpose, and to give any information concerning the botany of such specimens and the best way of raising them in quantities, should such a proceeding prove worth while."

One of the bulletins of the Ohio Experiment Station, after speaking of the difficulty which attends the testing of soils in the laboratory, says that the results of investigations on the spot are equally uncertain. "Take any single acre of ground for illustration. An open glade in the original forest may have permitted the wind to sweep away its winter coverlet of leaves, and they may have lodged in a thicket of underbrush adjoining, carrying stores of potash and phosphoric acid with them. Such a glade may have been for centuries the pasturing ground of deer. It would then accumulate nitrogen, but would lose potash and phosphoric acid through an additional channel, while the thicket would accumulate these in excess of nitrogen. The growth of a surface-rooting tree in one spot, may have drawn upon the adjacent surface-soil for supplies of potash; that of a tree with a deep tap root in another may have drawn its support largely from deeper layers of the soil and also have opened a way for drainage. A slight depression of the soil here may have received added fertility in the waste from a slight elevation there, and he who has studied the soil carefully, especially where its levels are shown by the melting of snow when the ground is frozen, will have detected irregularities of level unsuspected by the casual observer."

An admirable system for labeling the trees and many of the important shrubs in the National Botanic Garden in Brussels has been adopted. Sheets of stiff metal twelve inches by eight are covered on the outer surface with white enamel, on which, at the top, are printed the Latin name of the plant, with the best known French and Flemish names below. Under the name a map of the continent to which the plant belongs is drawn in black lines, and the area of its distribution marked in red. This is practically the same system of labeling as that which has been in use for several years in the Jesup Collection of North American Woods in the Natural History Museum of this city, and which was awarded last year a medal of the Paris Exposition. The labels in the Paris Garden are attached to large trees by a small screw and are placed on a level with the eye. For plants which are not large enough to carry the label it is fixed at the top of a stout iron rod placed before them. The metal used for the label is stiff enough to prevent it from being easily bent or broken, although the authorities complain that the enamel is sometimes cracked and defaced by boys throwing stones at the labels. One of the garden staff is constantly employed in preparing these labels, which are produced at what seems the surprising low price of about one franc each.

An interesting picture, recently published in the *Revue Horticole*, shows how the Japanese, not content with dwarfing and distorting plants, sometimes cause them to simulate a totally alien manner of growth. It was drawn from a specimen exhibited at the International Exhibition last summer and represents *Aspidium lepidocaulon*, a Fern which the botanical dictionaries describe as stemless or nearly so, with fronds from one foot to a foot and a half in length, which often have a long filiform tip furnished with a terminal bud ready to take root. In the picture aforesaid there appears to grow from the soil in the pot a rough, swollen stipe as large as a cocoanut; from this spring, at diverging angles, two similar bodies, and from the top of each of these grows a luxuriant tuft of fronds. When the seemingly single plant was examined the process of its manufacture was made clear. Several plants with their roots had been taken, and the roots wrapped, up to the springing of the leaves, in compressed Moss, forming ovoid bodies, two of which seemed to grow from the one beneath them, the different plants being so placed, at various heights, as to simulate ramifications. These ovoid bodies had then been carefully wrapped in Palm fibres so delicately manipulated as to appear a natural envelope. Thus the Ferns were actually growing in the concealed Moss while seeming to be nourished from the earth in the pot through the large artificial (but natural-looking) stipes.

The Madroña (<i>Arbutus Menziesii</i>).....	515

The Madroña.

THE forests of North America contain two broad-leaved evergreen trees unsurpassed by those of any other temperate region of the earth's surface. They are the Great Magnolia, the glory of our southern forests, the handsomest and perhaps the most esteemed of all garden decorations, and the Madroña of the humid coast-region of Oregon and California. This is the *Arbutus Menziesii*, and by far the largest and most beautiful of the trees of the small genus to which it belongs, and one of the most remarkable and interesting of all the trees of the northern Pacific forests.

The genus *Arbutus* is common to the Old World and the New. One species is widely distributed through southern Europe from Spain to the Caucasus, ascending the west coast of the continent to Ireland, where it abounds in the neighborhood of the Lakes of Killarney. This species, the *Arbutus Unedo* of botanists, the so-called Strawberry-tree, has been cultivated from time immemorial in gardens, which it decorates with its evergreen foliage and handsome white flowers. These appear late in the autumn simultaneously with the ripening of the brilliant red fruit of the previous year. A second species, *Arbutus Andrachne*, inhabits the Levant, and is sometimes seen, too, in the gardens of southern Europe. But the headquarters of the genus in the multiplication of the species is Mexico, where several little known and imperfectly defined forms exist. Two of these extend north of the boundary of the United States, one into Texas, where it occurs in the western part of the state in a few isolated stations, and the other into Arizona, where it grows high up on some of the mountain ranges in the extreme southern part of the territory. The home of the Madroña or of its ancestors was once, no doubt, among the Mexican mountains, where species which much resemble it still occur; but now it ranges far northward from the Santa Lucia Mountains, in southern California, to the islands which guard the coast of British Columbia. In favorable situations in forests influenced by the fogs and rains attracted to the coast from the surface of the Pacific, it attains a great size, shooting up to a height of more than 100 feet, and forming, when it grows

surrounded by other trees, a tall, stout trunk three or four feet in diameter. Such a specimen appears in our illustration on page 515. It is made from a photograph of a forest-scene in California, sent by Mr. C. H. Shinn.

Often the Madroña appears on the dry foot-hills east of the outer coast range, where the forest is open, and the trees stand at a considerable distance apart, assuming a round-topped, spreading habit of growth. Developed under such conditions the Madroña looks at a little distance like some great Apple-tree. A surprising specimen of this sort—the greatest Madroña-tree in existence, perhaps—is growing near the reservoir in the town of San Rafael, across the bay from San Francisco. Great horizontal branches shoot out from the short and immensely thick trunk, and support a broad, symmetrical mass of foliage. This tree, which is certainly one of the marvels of arborescent growth, might well be taken for one of the great Live Oaks of California, which hardly surpass it in breadth of branch or in density of foliage. Its portrait will appear later in this journal, and will serve to illustrate one form of the Madroña which, south of the Bay of San Francisco, grows less vigorously than at the north, becoming smaller and smaller, until toward the southern limits of its distribution it is reduced to a low, stunted shrub.

The bark of the Madroña, like that of the other species of *Arbutus* and of the nearly related *Manzanitas*, which abound in California, is its most striking feature. It is very thin and smooth on the branches and young trunks through its separation into thin plates, and bright red-brown. On old trunks only, especially near their base, it becomes thick, furrowed and dark colored. In the species which is found in Arizona the mature bark is nearly white, or not unlike in color the bark of the White Oak, which it further resembles in the small, thin scales into which the surface separates. The bright red color of the branches of the Madroña heightens the effect of the ample ovate leaves, which are four or five inches long by half that breadth. They are thick and beautifully lustrous on the upper surface and pale on the lower. The flowers, which are shaped like those of some of our Blueberries and *Andromedas*, for *Arbutus*, like these, belongs to the Heath family, are white or greenish white, and are produced in large, terminal clusters or racemes. They unfold in early spring, and are followed by masses of orange-red berries, which brighten the trees for weeks in the late autumn.

The Madroña was naturally one of the first trees of our Pacific forests to attract the attention of botanists. Archibald Menzies, who is commemorated in its scientific name, the Scotch physician and naturalist, who sailed with Vancouver from 1790 to 1795, and who discovered and carried to England another remarkable tree, the *Araucaria* of Chili, first detected it, probably, near the mouth of the Columbia River. Thirty years later David Douglas recognized its value and sent seeds to England from the same region.

Economically the Madroña is a tree of considerable value, yielding a hard, straight, close-grained wood of a handsome pale red color, of real value in cabinet-making, provided sufficient care is taken in properly seasoning it. It is already largely consumed in the manufacture of charcoal, and the bark furnishes excellent tanning material. It is as an ornamental tree, however, that the Madroña first claims attention. It is not an easy tree to manage always, as the absence of fibrous roots makes any but nursery-grown specimens difficult to transplant. It is not hardy in the eastern states, and in Europe it will probably develop its greatest beauty only in such exceptionally warm and moist regions as Devonshire, the south of Ireland, the islands of the British Channel and some parts of western France. Specimens are occasionally seen in these favored localities, but we have no record of any large or exceptionally fine ones.

The Californians, who possess within their own territory the most wonderful as well as some of the most beautiful trees known to man, unfortunately neglect the material they have ready to their hands and ransack

the world for exotic trees with which to beautify their homes; and California valleys are fast becoming converted into groves of Eucalyptus and Acacias, while one looks in vain outside the rapidly disappearing forests for the native trees, which are world-wide wonders, and which ought to be the pride of every true Californian. There may be seen, to be sure, at every turn groves and specimens of the Monterey Pine, one of the ugliest of all its race, and of the beautiful Cypress of Monterey. These two trees are almost the most local and restricted of all American trees in natural distribution, but, strangely enough, they are easily propagated and transplanted and grow in cultivation at first with surprising rapidity, so that they are now scattered from Victoria to San Diego. But one looks almost in vain in the gardens of California for the other trees which give character, value and beauty to the forests of the state—the Oaks, the Pines, the Firs, the great Broad-leaved Maple, the Evergreen Laurel, the Manzanitas, and all the host of smaller trees and shrubs with curious foliage and beautiful flowers. But sooner or later the Californians will appreciate the beauty of their own forests and realize the value of the trees of California for the decoration of the gardens and parks of California, and then the Madroña will certainly attain the position it deserves among ornamental trees.

As we recall all the beauty of this marvelous tree seen in some sheltered forest glade of the north-west coast, we recall the words which the venerable Albert Kellogg, who loved the trees of his adopted state so well and studied them so faithfully through long years, once spoke of the Madroña; and to his question, "whether imagination, fiction or fancy can portray to itself a sylvan object more wonderful, more chaste or more charming," we can find no answer but one of negation.

The Proposed State Forest-Park.

RECENT articles in the New York *Tribune* regarding Adirondack matters mention the increase in the price of timber-lands as one of the results already produced by the extension of the railroads in the Adirondack region. This increase is a natural consequence, and has long been foreseen by intelligent observers of the course of things in the northern part of the state. This inevitable advance in prices will render more difficult the acquisition of lands for the proposed State Park or Forest Reservation, but it is an advance which is likely to continue for some time to come. It is not probable that the lands needed for a reservation for the protection of the sources of the great water-ways of the state can ever be acquired more cheaply than now, unless the state waits for more of the land to be burned over and completely desolated and destroyed; but this process would also destroy the rivers which the park is intended to preserve.

In his message to the Senate last winter the Governor recommended that the limits within which lands are to be retained by the state for the purposes of a state park should be settled and defined, and that they should include the wilder portion of the region covering the mountains and lakes at and around the head-waters of the several rivers which have their sources there, including the Hudson River. This recommendation was referred by the joint action of the two houses of the Legislature to the State Forest Commission, with instructions to make a thorough investigation of the possibilities of such an undertaking, and to report to the Legislature its conclusions thereon, and its recommendations as to the most effective methods to be employed to accomplish the end in view—the establishment of a State Park—together with any pertinent facts within the knowledge of the Commission relating to the general subject of forest-preservation or extension, and also to report the number of acres or square miles of land essential to fulfilling the requirements of a suitable reservation or park and the probable cost thereof.

This is the only plan of action, or suggestion of a plan, looking to the establishment of a state forest-park which

has been presented to the public. The Commission has been making investigations during the summer, and in its forthcoming report it will, of course, present the main proposition in an affirmative form. That is, it will recommend the establishment of a state forest-park, so that all those who are in favor of that object can unite in support of the essential idea of the report, which is in every way desirable.

Other plans may be proposed after the Commission's report has been presented to the Legislature. Full discussion, not only in the Legislature but in the press of the state, will be necessary in order to develop the popular judgment regarding the enterprise. There appears to be an increase of public interest in the subject, and a more general impression than hitherto that something is likely to be done. It is to be hoped that this impression is well founded, and that some plan will be presented in support of which all who feel an intelligent interest in the destiny of the Adirondack forest-region can heartily unite. It is not likely that the expectation of the Governor, that "a state park from fifty to seventy miles square can be obtained by the State in that region at comparatively trifling expense," will be realized. The necessary cost of the land of such an area will not be trifling. But it will be less this year than in ten or twenty years from now, and for a possession so valuable as a forest-reservation of this extent around the sources of the principal rivers of the state the people of New York should be willing to pay a reasonable price.

THE annual report of the General Commissioner of the Land Office of the United States has appeared. Judge Groff, the Commissioner, devotes considerable attention to the forest-problem. The means at the disposal of the Secretary of the Interior for protecting the forest-property of the nation is acknowledged to be entirely inadequate; and it is found that the most valuable timber on the public land is being exterminated unlawfully wherever forests exist. This is not a new discovery. The same thing has been stated more than once in previous reports from the same office; and it has been a notorious fact for years with all persons familiar with the actual condition of our western forests that, unless energetic measures are adopted for their protection, the practical extermination of these forests is only a matter of time. This subject has been brought to the attention of Congress year after year; bills looking for forest-preservation have been introduced again and again, and have met with the hearty approval of intelligent men in all parts of the country. Congressional indifference and local opposition from the forest-region, fostered by men directly interested in forest-destruction, have prevented the passage of any proper legislation for the protection of the nation's forests. This is a matter of urgent and commanding importance to the well-being of the whole country, and it cannot be safely postponed. Delay is danger, and danger which is real and impending, although not always readily understood by persons who are not familiar with the topographical and climatic conditions of the western part of this continent, which must become uninhabitable as soon as the forests which protect the valleys from the heights above them are swept away.

The use of the army of the United States to protect the national forest-domain until some better plan has been devised has been suggested by this journal, and, as yet, no better scheme has been proposed. It promises efficiency and has the advantage of economy. The press of the country and many thinking men sanction it with their approval.

"Great attention must also be given to the situation in which a building is to stand. A feudal castle in the middle of a wheat field—as at Machern, near Leipzig—is almost comic; as is an Egyptian pyramid in a gay Birch grove or a pastoral landscape, or a thatched hut surrounded by a French parterre.

"In the same way pointed Gothic architecture appears out of place when set among pointed Firs or Lombardy Poplars, while it is in place among round-headed Evergreens or Oaks and Beeches."—From Pückler-Muskau's "*Andeutungen über Landschafts-gärtnerei*."

Cape Cod Cranberries.

CRANBERRY-GROWING is unique among our horticultural industries. All a man's knowledge of gardening and fruit-growing in general is useless when he undertakes to grow this berry. He must lay aside his common notions of soils and tillage, and even discard the very tools which from boyhood he has considered essential to any kind of cultivation.

The Cranberry-growing sections of the country are few and scattered. The Cape Cod district is the pioneer ground of Cranberry culture, and it still undoubtedly holds first rank in general reputation. In provincial parlance the Cape Cod region includes all the peninsular portion of the state, beginning with the lower and eastward projection of Plymouth County. The Cranberry region extends from this eastern portion of Plymouth County eastward to the elbow of the peninsula, or, perhaps, even farther.

Upon one of the upper arms of Buzzard's Bay is the old town of Wareham. Here the tides flow over long marshes bordering the inlet, and rise along the little river which flows lazily in from the Plymouth woods. Here the sea-coast vegetation meets the thickets of Alder and Bayberry and Sweet Fern, with its groups of Wild Roses and Viburnums. And in sheltered ponds the Sweet Water Lily grows with Rushes and Pond Weeds in the most delightful abandon. In the warm and sandy glades two Dwarf Oaks grow in profusion, bearing their multitude of acorns upon bushes scarcely as high as one's head. The Dwarf Chestnut-Oak is often laden with its pretty fruits when only two or three feet high, and it is one of the prettiest shrubs in our eastern flora.

Driving northward over the winding and sandy roads into the town of Carver, where the largest Cranberry plantations are located, our journey lies in the Plymouth woods. And here the surprises begin! We see no fields of Corn and Grass, and snug New England gardens, and quaint old houses whose genealogies run into centuries; but we plunge into a wilderness!—not a second growth, half-civilized forest, but a primitive waste of sand and Pitch Pine and Oaks! The country has never been cleared, and it is not yet settled! And in its wilder portions deers are still hunted and lesser game is frequent! And only fifty miles away is the bustling Hub of the universe!

This Cape Cod region is but a part of the sandy waste which stretches southward and westward through Nantucket, along the north shore of the sound and through a large part of Long Island; and essentially the same formation is continued along the New Jersey seaboard. Similarities of soil and topography are always well illustrated by the plants they produce. The Pine-barren flora of New Jersey reaches northward into the Cape country, only losing some of its more southern types because of the shorter and severer seasons. But more diligent herborizing will no doubt reveal closer relationship between New Jersey and Cape Cod than we now know. An instance in my own experience illustrates this. The Striped Sedge (*Carex striata*, var. *brevis*) is recorded as a rare plant, growing in Pine-barrens from New Jersey southward, and yet in these Plymouth woods, in the half sandy marshes, I found it growing in profusion. Even eastern Massachusetts is in need of botanical exploration! So the floras run along this coast; and it is not strange that Cape Cod and New Jersey are both great Cranberry producing regions.

The country comprises an alternation of low, sandy elevations, and small swamps in which the Cassandra, or Leather-leaf, and other Heath-like plants thrive. The Pitch Pine makes open and scattered forests, or in some parts Oaks and Birches and other trees cover the better reaches. Fire has overrun the country in many places, leaving wide and open stretches carpeted with Bearberry (*Arctostaphylos*) and dwarf Blueberries. Clear and handsome little lakes are found in some parts of the wilderness, and everywhere one finds clear and winding brooks, abounding in trout. And over all the open glades the great-flowered Aster (*Aster spectabilis*) is brilliant in the autumn sun.

It is in the occasional swamps in this sandy region that the Cranberry plantations or "bogs" are made. In their wild state these bogs look unpromising enough, being choked with bushes and brakes. I am filled with a constant wonder that the sandy plains are not also utilized for the cultivation of Blueberries. These fruits now grow in abundance over large areas, and they are gathered for market. It would only be necessary to enclose the areas, protect them from fire and remove the miscellaneous vegetation, to have a civilized Blueberry farm. Certainly Cranberry and Blueberry farms would make an interesting and profitable combination. The expense of growing the Blueberries would be exceedingly slight, and

the crop would be off before Cranberry picking begins. To be sure, wild berries are yet common, but they would not interfere with the sale of better and cleaner berries which would come from improved plantations. Wild Cranberries are still abundant over thousands of acres, and the production of cultivated berries is rapidly increasing; yet the price has advanced from fifty cents and one dollar per bushel, with an uncertain market, fifty years ago, to fifteen and twenty cents a quart.

The largest cultivated bog in existence lies about six miles north of Wareham, and is under the management of A. D. Makepeace, one of the oldest and most experienced Cranberry growers in the country. This bog is 160 acres in extent. Other bogs in the vicinity belong to the same management. These bogs are all as clean as the tidiest garden. The long and level stretches, like a carpet strewn with white and crimson beads, are a most pleasing and novel sight. Here in early September a thousand pickers camp about the swamps, some in temporary board cabins, but most of them in tents. The manager furnishes the provisions, which the campers cook for themselves, and he rents them the tents. One hundred and twenty pickers constitute a company, which is placed in charge of an overseer, and each company has a bookkeeper. Each picker is assigned a strip about three feet wide across a section of the bog, and he is obliged to pick it clean as he goes. The pickers are paid by the measure, which is a broad six-quart pail with ridges marking the quarts. Ten cents is paid for a measure. There is wide variation in the quantity which a picker will gather in a day, ranging all the way from ten measures for a slow picker to forty, and even fifty, for a rapid one; and in extra good picking seventy-five measures have been secured.

Various devices have been contrived for facilitating Cranberry picking. The Cape Cod growers like the Lumbert picker best. This is essentially a mouse-trap-like box with a front lid rising by a spiral spring. The operator thrusts the picker forward into the vines, closes the lid by bearing down with his thumb, and then draws the implement backward so as to pull off the berries. Perhaps a fourth of the pickers use the implements. Children are not strong enough to handle them continuously, and where the crop is thin they possess little advantage. Raking off the berries is rarely practiced in the Cape Cod region. It is a rough operation, and it tears the vines badly. Late in fall, if picking has been delayed and frost is expected or pickers are scarce, the rake is sometimes used. An ordinary steel garden rake is employed. The berries are raked off the vines, and the bog may then be flooded and the berries are carried to the flume, where they are secured.

This picking time is a sort of long and happy picnic—all the happier for being a busy one. The pickers look forward to it from year to year, and are invigorated by the change and the novelty.

The berries must now be sorted or "screened." If there are no unsound berries, the fruit can be fairly well cleaned by running it through a fanning mill; and some growers find it an advantage to put all the berries through the mill before they go to the hand screeners. A screen is a slatted tray about six feet long and three and a half wide at one end and tapering to about ten inches at the other, with a side or border five or six inches high. The spaces in the bottom between the slats are about a fourth of an inch wide. The screen is set upon saw-horses, and three women stand upon a side and handle over the berries, removing the poor ones and the leaves and sticks, and working the good ones toward the small and open end, where they fall into a receptacle. The berries are barreled directly if they are not moist, but if wet they are first spread upon sheets of canvas—old sails being favorites—and allowed to remain until thoroughly dry.

The cultivated Cranberry is a native of our northern states. It was first cultivated about 1810, but its culture had not become general until forty or fifty years later. The berries naturally vary in size and shape and color, and three general types, named in reference to their forms, were early distinguished—the Bell, the Bugle and Cherry. So late as 1856 there was no record of any particular named varieties aside from these general types. But there are many named sorts in cultivation now. Mr. Makepeace showed me seven varieties in his largest bog.

The common favorite is the Early Black, valuable because it comes in three weeks ahead of the medium sorts. Picking begins upon this variety about the 1st of September here. When fully ripe, the berries are purple-black, and for this reason they are favorites with consumers, for it is a common though erroneous notion that pale berries are unripe. In late fall the foliage of the Early Black assumes a purplish tinge, which quite readily distinguishes it from any other variety.

The Dennis is a bugle berry, of good size, productiveness and bright scarlet color. The fruit is picked late in September and early in October. The foliage is darker than that of the Early Red.

The McFarlin, an oval, dark red berry, is probably the largest late berry grown.

The Gould is a productive pear-shaped berry, of medium season, with a bright purple fruit and light colored foliage.

The Lewis is probably the most brilliantly colored of the Cranberries. It is a very bright glossy scarlet, medium in season and pear-like in shape.

The Franklin is a comparatively new pear-shaped sort, as late as Dennis, purple-red, with a high habit of growth. It appears to have little to recommend it above older sorts.

A new berry which Mr. Makepeace showed me appears to combine more merits than any berry which I have ever seen. Some twelve years ago he observed the original plants in a neighbor's bog, occupying a space about six feet square, and he procured a few cuttings. The small bog which he now has of it is well worth a journey to see. The berries are unusually large, cherry-shaped, a little later than Early Black, and a bright rose-purple. It is probably the largest early berry. I take pleasure in calling it the Makepeace.

It is an arduous duty to subdue a wild bog. The bushes and trees must be removed, roots and all, and it is usually necessary to remove the upper foot or so of the surface in order to get rid of the roots, bushes and undecayed accumulations. This process is termed "turfig." The turf is commonly cut into small squares and hauled off. It is necessary to leave the surface level and even, in order that all the plants may have an equal chance and thereby make an even and continuous bed, and to avoid inequalities in flooding. Although the Cranberry thrives in swamps and endures flooding at certain seasons, it nevertheless demands comparative dryness during the growing and fruiting season. The swamp must therefore be drained. Open ditches are cut at intervals of four or five rods, about two feet deep, and these lead into the main or flooding ditch. It is also often necessary to run a ditch around the outside of the bog to catch the wash from the banks. The areas enclosed within the intersections of the ditches are called sections, and each section is planted to a single variety. The main ditch is usually a straightened creek, or it carries the overflow from a reservoir which may be built for the purpose of affording water to flood the bog. Growers always divert a creek through the bog if possible. In the Cape Cod districts these creeks are often clear trout brooks. The main ditch is strongly dammed to allow of flooding.

Before planting, the bog is sanded. This operation consists in covering the whole surface with about four inches of clean and coarse sand, free from roots and weeds. The chief object of sanding is to prevent too rapid growth and consequent unproductiveness of vines. In wild bogs, the Cranberry rarely roots deeply in the muck, but subsists rather in the loose sphagnum moss. Vines that grow in pure muck rarely produce well.

The sand also serves as a mulch to the muck, mitigating extremes of drought and moisture. It also prevents the heaving of the vines in winter, and it aids in subduing weeds. Every four or five years after the bog begins to bear it is necessary to resand it, in order to maintain productiveness. These subsequent applications are light, however, seldom more than half an inch in depth. The Cape Cod bogs are fortunate in their proximity to the sand.

It was once the practice to plant Cranberry-vines in "sods," or clumps, just as they are dug from the swamps. There are several vital objections to this operation, and it is now given up. It is expensive, the vines are apt to be old and stunted, an even "stand" can rarely be secured, and many pernicious weeds and bushes are introduced. Cuttings are now used exclusively. These are made from vigorous runners and are six or eight inches in length. They are thrust obliquely through the sand, about an inch and a half or two inches of the tip being allowed to project. They are set in early spring, about fourteen inches apart each way. In two or three weeks they begin to grow, and in three or four years a full crop is obtained. The subsequent cultivation consists in keeping the bog clean. A small force is employed during the summer months in pulling weeds. Under ordinary conditions it costs from \$300 to \$500 per acre to fit and plant a bog.

There are those who contend that flooding is not necessary. It appears to be generally held that bogs are longer lived and more productive if judiciously flooded. The reasons for flooding, so far as I know, are five: (1) To protect the plants from heaving in the winter; (2) to avoid late spring and early fall frosts; (3) to drown out insects; (4) to protect from drought; (5) to guard against fire, which sometimes works sad havoc in

the muck. Mr. Makepeace prefers to flood but once a year, unless insects appear in serious numbers. He lets on the water in December and draws it off in April or early in May. Just enough water is used to completely cover the vines in all parts of the bog.

There are many hindrances to Cranberry growing. The chief are spring and fall frosts, hail, numerous insects and some fungous diseases. During the summer season the bogs are not flooded, and insects must be kept in check by insecticides. Tobacco water is commonly used. The liquid is applied with hand pumps from tanks. It is supposed that it has some value as a fertilizer also.

Fifty barrels per acre is a good crop of Cranberries, yet 200 barrels have been produced. The grower usually gets from \$5 to \$10 per barrel of 100 quarts. It does not appear to be known how long a well handled bog will continue to be profitable, but Mr. Makepeace assures me that he knows a bog thirty years old which is still in good condition.—*Professor L. H. Bailey in American Garden.*

New or Little Known Plants.

Clematis Stanleyi.

ALTHOUGH discovered about fifty years ago, and figured in Hooker's "Icones Plantarum," t. 589, where it is described as "the handsomest species of an extensive and handsome genus," this Clematis has only recently been introduced into cultivation. It has already been noticed in GARDEN AND FOREST as being in flower at Kew, and our illustration (see p. 513) has been prepared from a plant there. It appears to be not uncommon in the eastern provinces of the Cape; Burke, who collected for Lord Derby, in compliment to whom the species was named, having first found it in Macalisberg. The Kew plants were raised from seeds collected in the Transvaal by Mr. E. Galpin, who described the plant as "a shrubby Clematis, not more than three feet high, with deeply cut silky leaves and large pinkish or pale purple flowers. The fruit when ripe is a beautiful object, as elegant as a bunch of ostrich feathers and silvery white. At first I thought it was an Anemone. It is a very ornamental plant, and may, by crossing it with the garden Clematises, produce a new race."

In a recent communication Mr. Galpin states that the plant is abundant at high altitudes where frost is frequently known, and suggests, therefore, that it may prove to be hardy in England. Some plants placed outside last year at Kew perished in the winter. The best plants are those which have been from the first in a border in a sunny greenhouse. These have grown a yard high, the leaves are almost as silvery as those of the Silver-tree itself, and the flowers have been abundant since the middle of July. A bed of plants in a sunny position out-of-doors has been only moderately successful, the summer weather this year in England having been unfavorable to plants which enjoy sunlight, warmth and not too much moisture. There is every prospect of this Clematis proving a first-rate garden-plant; if it will grow well outside, and flower as well as it does at the Cape, it will be almost as useful as *Anemone Japonica*. The whole plant is clothed with a silky tomentum, which in the sun gives it an attractive silvery sheen. The roots are fleshy, the stems tufted, herbaceous, branching freely from below, erect; the leaves opposite or alternate, six to nine inches long, bipinnate, the pinnæ variable in size and lobing. The flowers are terminal and axillary, the peduncles are six inches long, erect, curved near the top, and each bears one flower, which is two and a half inches across, cupped at first, almost flat before fading, the segments thick and fleshy, broadly ovate, with prominent veins. The color varies from dull purple to rose, and some of the plants are almost white flowered. The stamens are in a large cluster and yellow. Every flower is followed by a head of fruit. The stems are annual, and the plants should be kept on the dry side whilst resting. They start into growth in early spring, and as the first lot of stems flower a second lot is pushed up from the base of the plant, which are in bud ere the first lot of flowers have faded.

Fig. 65.—*Clematis Stanleyi*.—See page 512.

New Orchids.

MASDEVALLIA FULVESCENS, Rolfe, is a pretty little species introduced from New Granada by Messrs. Fred. Horsman & Co., of Colchester. It is apparently allied to *M. infracta*, Lindl., but with more brightly colored flowers. These are of a light buff yellow, shading into purple-brown on the con-

stricted sides of the throat. It is described and figured in the *Gardeners' Chronicle*, September 25th, p. 325, Fig. 65.

MASDEVALLIA × *STELLA*, Rolfe, is a very pretty little hybrid, raised by Captain T. C. Hincks, of Thirsk, Yorkshire, from *M. Estrada*, fertilized with the pollen of *M. Harryana*, and which flowered for the first time during the present summer. It is quite intermediate between the two parents, the tall scapes,

the lateral sepals, the color resembling the pollen parent, while the other floral characters, and also the leaves, more nearly resemble those of the mother plant. It is a distinct and elegant little hybrid.—*Gardeners' Chronicle*, September 20th, p. 325.

LELIA × *JUVENILIS*, A. Bleu, is a handsome hybrid, raised from *Lælia Perrinii* fertilized with the pollen of *L. pumila*, in the collection of Mr. Alfred Bleu, of Paris. It is quite intermediate in character, both in the organs of vegetation and in the flower, though in this latter particular the descent from *L. Perrinii* is the most clearly marked. The sepals and petals are of a rosy lilac shade, as are also the side lobes of the lip, while the throat is white and the front lobe of a deep carmine shade. The peduncle bears a single flower.—*Orchidophile*, August, 1890, p. 240, with plate.

LELIO-CATTLEYA × *PROSERPINE*, Rolfe, is a pretty little hybrid raised in the establishment of Messrs. James Veitch & Sons, of Chelsea, by Mr. Seden by crossing *Lælia pumila* *Dayana* with the pollen of *Cattleya velutina*. The flower is over three inches in diameter, decidedly approaching the pollen parent in shape, though with the color, also the habit of the plant, more like the seed parent. It received an Award of Merit from the Royal Horticultural Society on August 26th last.—*Gardeners' Chronicle*, September 27th, p. 352.

CATTLEYA GASKELLIANA PICTA, Rolfe, is a striking variety in the collection of the Right Hon. J. Chamberlain, of Birmingham, in which the petals have a broad central band, with a few radiating branches of light purple on a lilac ground. The sepals are less distinctly variegated with the same colors.—*Gardeners' Chronicle*, September 27th, p. 352.

Kew.

R. A. Rolfe.

The Coco-de-Mer.

THE successful germination of several nuts of the Coco-de-Mer or Double Cocoanut (*Lodoicea Seychellarum*) deserves to be recorded as an event of more than ordinary interest. These nuts have been known to germinate at Kew and elsewhere before now, but they have invariably perished before the first stage of germination was passed. At Kew, however, there is now a plant with a leaf three feet long and nearly as wide, and having a mass of healthy roots, whilst two other seedlings are in a most promising condition.

The Coco-de-Mer is perhaps the most remarkable member of the Palm family. In every character, from its seeds to its gigantic crown of leaves, it is Titanic. For centuries its history was involved in mystery. Its enormous seeds found floating on the Indian Ocean were supposed to be the product of a tree which sailors declared they had seen growing beneath the sea. They were claimed as royal property whenever found, and sold for enormous prices, a ship laden with merchandise having been given for a single nut.

The discovery of the Seychelle Islands in 1743 revealed the true source of these mysterious nuts. Even this, however, did not entirely divest the tree of its supernatural character, for only a few years before his death General Gordon declared his belief that this Palm was the Tree of Knowledge of Good and Evil which stood in the Garden of Eden. The General united an ardent love of plants and considerable botanical knowledge with his military duties, and during several years' residence in the Seychelles, about ten years ago, he made numerous drawings of the Coco-de-Mer, and elaborated his theory that the small island of Praslin, where this Palm is native, was the site of the Garden of Eden. His drawings and notes are now at Kew.

Putting aside all fabulous stories relative to the Coco-de-Mer, and viewing it in its purely botanical character as a Palm, it yet remains a vegetable wonder. Its restriction to two or three very small islands in the Seychelles group, when considered along with its wide difference from all other Palms, gives it a position of the highest importance in geographical botany. The value of its nuts for museums and as ornaments, with the use of its young leaves in basket-making by the natives, threatened its extermination, and it was only when the Linnæan Society made a strong appeal to the Colonial authorities that the danger of its becoming extinct was averted.

The height of the mature trees is from 60 to 150 feet. The trunk is smooth, marked with rings, and about a foot in diameter, except at the extreme base, where it is swollen, onion-like, and surrounded by a hard shell-like covering like an immense socket. The leaves form an enormous crown, each one being twenty feet long by ten feet wide in the blade, and the pole-like petiole proportionately large and strong. The male and female flowers are borne by different plants. The male inflorescence is in the form of a gigantic willow catkin,

six feet long by four inches in diameter. The females are four feet long, and each spike bears from six to ten fruits. These are in the form of huge acorns, and when mature weigh from twenty-five to thirty pounds each. The seed is about a foot long by two and a half feet in circumference. It is deeply two-lobed at both ends and channelled down the middle, so that it looks like two oblong nuts joined by their sides. The nuts are seven years in ripening and about two years in germinating. The trees begin to bear when about forty years old and are said to reach maturity in 120 years.

The germination of the nuts is very remarkable. From between the lower lobes a stout radicle is pushed to a length of about four feet (General Gordon says twelve feet). This thickens to a circumference of a foot or so near the end, where it finally splits to allow the growth of the plumule, which is on the same large scale as everything else in this Palm.

If Kew succeeds in growing plants from these promising seedlings it will be an achievement beside which the flowering of the Giant *Amorphophallus* and the cultivation of the *Welwitschia* will count for very little.

The Palms of the Seychelles are amongst the choicest of those cultivated in gardens. The *Stevensonia*, *Verschaffeltia* and the *Latantias* (not *Livistonas*) are unequalled for nobleness of character. There are large specimens of all the Palms known in the Seychelles at Kew, except, of course, the *Lodoicea*.

Autumn Work in the Hardy-Flower Garden.

WITH the closing up of out-door work no time should be lost in preparing, as far as possible, for next year's display. Those who intend making borders of hardy perennials, or even planting in a limited way, should bear in mind that a border of this description is not for a season only, but that this class of plants are planted to stay and that the preparation must be better than that made for annuals. If the soil be uniformly heavy and retentive, part of the border should be made drier by the liberal application of coarse sand and lime rubbish. Many plants thrive admirably in a dry soil which would not grow in that of a moist nature, and vice versa. The right kind of soil is, therefore, the first consideration. Another point worth remembering is that an herbaceous border, when once planted, should never be disturbed with a spade, except to make changes in it; for even to one understanding border-plants it would be impossible to use a spade among them without injury. It is generally best, in soils of a retentive nature, to stir the surface of the beds in spring, but the use of the fork had better be deferred until the ground is in good condition, and then many of the plants will have started into growth, and may easily be seen and injury avoided. Where plants are to be procured or replanted it should be done at once, before the soil loses more of its warmth, so that the plants may become well rooted before cold weather. At this time the soil is often warmer than the air above it, and it is surprising how newly planted things take hold and establish themselves—much more readily than in spring, when the soil is cold for some time after the air has become warm enough to start into growth plants which are already established. Perennial plants require good soil, as they cannot be dug over in spring for the purpose of working in a fertilizer. The best way to keep them well nourished is to apply a good top-dressing of manure in the fall as soon as growth ceases; a uniform covering of four or five inches will not be too much, as, if the manure is well decayed, so that it may be cut with a spade, there will remain very little to be raked off in spring. When bulbs are planted it is best to have them as nearly as possible together, as these need somewhat different treatment from herbaceous rooted plants. For instance, such bulbs as *Iris reticulata*, *I. Anglica*, the tuberous rooted *Anemones*, Spanish *Iris*, Californian *Lilies*, many Japanese and European kinds, and in fact any rare or tender bulbs, will be the better for a good coat of dry leaves; they should be covered with a spare sash or shutter, taking care to guard against the ingress of mice, which are very liable to make snug homes in such warm quarters. We have found that the best way to get rid of field mice is to soak wheat or corn in a solution of strychnine, the poison killing them at the first taste. In passing, it may be remarked that this has been found the best way to keep mice away from seeds. When first sown in pans we had endless trouble and vexation until strychnine was used.

A short time since it was advised to plant *Narcissus* nine inches deep. I had in mind soil of a sandy nature; but on examining the garden of a friend recently I quite agreed with

The Madroña (*Arbutus Menziesii*).—See page 509

him that Narcissi would not push their way through nine inches of red clay soil. With a wet, heavy soil it is best to prepare a plot for bulbs by adding plenty of sand, using also a good handful at the base of each bulb. Tritonias (Kniphofias), *Arundo donax*, Eulalias, *Anemone Japonica* and any plants of doubtful hardiness should be lifted now and wintered in soil in the cellar; the plants are always the better for it next year if planted out early in newly enriched soil.

Dahlias.

THERE are no more useful, showy and satisfactory flowers in the late summer and fall than the Dahlias. Continuing in bloom till cut off by the frost, they furnish a constant supply of bold, handsomely colored flowers until the Chrysanthemums come on. Probably no flower has been more subject to popular caprice, for the flower-loving public alternately takes up and discards the various forms. In some gardens the old double forms are still grown, but in most gardens one notes a change to the Pompons, Single, and lately to the Cactus forms. The latter are, of course, merely a reversion to the more natural types and such as readily come from seed. While the very double Dahlias are noble flowers, and mostly of pure colors, there is a formality about them which is not pleasing to many, especially when they are cut with short stems. So common is this habit of cutting that for some years I would not admit the flower to the garden, so firm was the impression of stiffness received from seeing the blooms at exhibitions. Probably many others are as unduly prejudiced. The Pompon Dahlias are a very satisfactory strain. The habit of the plants is dwarf; they are also free bloomers, with small flowers of a very useful size. A few years since some bright cultivator took advantage of the preference for single flowers of all kinds and reintroduced the single Dahlias as a new departure. These are generally brilliant in color and free-flowering, and they at once secured attention, and have become established favorites. Their merits are certainly great, for they are excellent for bouquets, though fading rather soon, and they are showy and free from stiffness. As garden plants they are ornamental, with the fault of bearing too many seed, and the necessity of keeping these cut off makes them somewhat of a care. The forms of single Dahlias now offered are innumerable, and it seems scarcely worth while to name them, as from a packet of seeds sown early in the year a great variety may readily be had. Latterly the Cactus varieties, as the semi-double kinds are called from their fancied resemblance to Cactus blooms, have been finding special favor, because, while free from the formality of the double kinds, they are more lasting, and do not so quickly go to seed as the single ones. Of these, Juarezii seems to remain the best of the dark red or crimson ones, though a somewhat shy bloomer. Constance and A. W. Tait are the best whites; the latter, a variety from Portugal, is an especially distinct flower, with serrated, graceful petals, more resembling a good, full, reflexed Chrysanthemum than a Dahlia. Mrs. Hawkins is a pleasing kind, with cream centre, shading to a delicate salmon-pink. William Pearce is a free, fine yellow. There are numerous varieties of Cactus Dahlias, but the above are kinds which may be had of most growers making a specialty of these plants. Mention might also be made of Gracilis Dahlias, a strain of single flowers with wonderful stripings, spots and variations, and well worth growing from seed.

Notes on Native Ferns.

Aspidium cristatum is a good Fern for cultivation in any light soil that never becomes very dry. A fine loam suits it well, or clay and peat will answer. Its natural home is usually moist, low grounds in a peaty soil. It seems to prefer the sun, and is frequently found near and about old stumps or decaying logs in low pastures or meadows. Its fertile fronds are tall and narrow and die early in autumn. The sterile ones are shorter and often almost survive the winter. Its variety, *Clintonianum*, is a much larger form, and grows mostly in Ash swamps. It is much like the typical species, except in size and in its preference for the shade. It is a handsomer Fern than the true *cristatum* on account of its size.

Aspidium Thelypteris grows in locations similar to those in which *A. cristatum* delights, but is much more abundant. Its stems are usually longer than the fronds. The fronds are of a delicate texture, and quickly wilt when cut, or die with the first frost. It spreads rapidly, and a few plants soon form a thick bed. It will thrive well in shade, but, when growing naturally, the best plants are frequently in the sun. It is one of the easiest Ferns to grow.

Aspidium aculeatum, var. *Braunii*, is a rare Fern, but not so rare as the preceding, nor is it difficult to grow. It seems to thrive in any ordinary garden-soil, in shade, and is a fine plant when well established. Small specimens are the best for planting, and they will soon attain full size. This Fern is found along the margins of cold mountain-brooks and in cool mountain-ravines of northern New York and New England. Its height varies from a few inches in small plants to more than two feet in the largest specimens; the dark green fronds have a chaffy stem.

Aspidium Noveboracense has medium sized fronds a foot or more in length, and three or four inches wide at the middle, from which they taper to both ends. They are of a light green color, thin, wilt quickly when cut and are killed by the first frosts. This species is most commonly found in moist, thickly shaded places, and it requires a light, moist, well drained soil and more shade than most kinds. It is easy to manage when properly placed.

Aspidium fragrans.—The Fragrant Fern is one of our rarest natives, and its natural home is always a peculiar one. It seems to require a situation where it can obtain the very small amount of moisture it needs principally from the surrounding atmosphere. Dry, shaded cliffs are its choice, with an atmosphere rather moist. Among the mountains there are fogs that rise and fall about such cliffs, and where the right conditions, so far as shade, etc., exist, it is sure to grow. But these conditions are rare. At Bolton Falls, Vermont, there are dry, shaded cliffs just above or near the falls. Here this Fern is found, and at a low elevation; for the mist from the falling water is just what is required to cool and moisten the atmosphere, and is no doubt essential to the existence of the plants. On the dry cliffs of the Saguenay River, in Canada, the Fragrant Fern grows larger and more abundantly than in any other place I have seen it. Here the plants are often more than twice as large as specimens from New England. It is a handsome evergreen plant, with numerous fronds from three inches to a foot in length by half an inch to two inches wide. The dried fronds have an agreeable odor, hence its name. I have never grown it, and I judge from its peculiar habitat that it is not easy to manage out-of-doors.

F. H. Horsford.

The Borsdorfer Apple.

IN discussing the varieties of winter fruit among our imported Russian Apples, the one numbered 402 in the Department list has often been referred to. I received cions of it from Mr. Aaron Webster, of East Roxbury, Vermont, some fourteen years ago, and with it a sample fruit, which exactly resembled a small Ben Davis. Mr. Gibb, in his careful review of the Department list of Russian Apples, printed in the Report of the Montreal Horticultural Society for 1883, quotes what I had written to him of this sample, and gives no other description, though he gives the favorable opinions of Mr. Sias, of Minnesota, and Mr. Tuttle, of Wisconsin, on the hardiness of the tree.

My trees of this variety were planted in an unfavorable place, not only for rapid growth, but also for getting any fruit, being set by the roadside; but I found with the first fruiting that it bore not the least resemblance to Ben Davis. The variety is a slow grower at best and disposed naturally to form a round, bushy head, requiring frequent pruning to produce that openness essential to high coloration of the fruit. This year I have had, and was able to gather, a good number of characteristic specimens; and it happened, as some of them lay upon the writing table before me, that in turning over the leaves of Downing's "Fruit Trees" the name of "Borsdorfer" arrested my eye, and reading the description, I was pleased to find this to be the very Apple in question.

Borsdorfer, as given in Downing, presents the infallible mark of wide distribution and general popularity in the number of its synonyms. In England it has received the names of King George III, Garret Pippin, Queen's and King. In France it is called Reinette Batard and De Misnie, also Le Grand Bohemien Borsdorfer. It has several German names, in all amounting to ten; and Downing, without saying whether it had then been brought to America, calls it "a celebrated German Apple," and gives this description: "Roundish oval, narrowing at the eye; skin pale yellow, with a full red cheek, sprinkled with a little russet; flesh yellowish white, very firm and crisp, with a rich, brisk perfumed flavor; November to February."

This agrees exactly with my Apple in every particular; but Downing omits so many other points which he always gives in describing a fruit he has seen, that it is fair to assume that it first reached this country in the Department importation.

The cavity and basin of this apple are small and shallow, with some russet about both. The stem is slim, and about an inch long. Basin corrugate, calyx closed. A marked characteristic is the large, but not numerous dots, brown on the yellow skin, dark on the colored part. Core medium, seeds short, plump and light colored. The high piquant flavor is notable, even before the fruit becomes mellow enough to be eatable. I think the season will be December to April in New England—and here we have, if not a Russian, at least an iron-clad apple of high quality and a good keeper. Being so fair and handsome, and little, if any, smaller than Fameuse, I do not see why it will not be a good commercial apple. The rather dwarf habit and compact growth of the trees make it a good garden variety.

Newport, Vt.

T. H. Hoskins.

Strawberries.—Character of growth has to be considered in our estimate of Strawberries to a greater degree than has been my practice at least. My favorite late berry is the Summit. But it makes runners so very slowly that I find it hardly possible to keep up a bed of them. On the other hand, Crystal City is such an enormous multiplier that it makes very quickly a solid mat and is unable to produce good fruit. Going over my beds to select what I should call really good growers, making rows readily, but not too rampant, I should select Bubach No. 5, Cumberland and Haverland. Sharpless is on my soil generally a model, but not always; I am obliged to renew them oftener than I like. I can report on the growth of some of the newer berries as follows: Mrs. Cleveland makes fine growth on clay soil; Michel's Early fine; Eureka perhaps better yet; Lady Burk as good. Gypsy makes medium plants, and Crawford, Viola and Warfield are no more than medium. Luella has shown up poorly. Of Thompson's seedlings I have 4, 52, 54, 7, 9, 51. These are all making thrifty growth.

Clinton, N. Y.

P.

Hymenocallis macrostephana is the most robust as well as the most beautiful and fragrant of all the species of the genus. The large, pure white, deliciously scented flowers are arranged in dense umbels raised well above the leaves, which are about two or two and a half inches long, oblanceolate, and bright green, and in themselves exceedingly decorative even when the plant is not in flower. My plant, received a few years ago from B. S. Williams, of London, blooms regularly every year in September. The bulb has attained a large size, but as yet has made no offsets. It is grown in a compost consisting of equal parts of well rotted stable manure, leaf mould and sand. All the *Hymenocallis* in my possession—namely, *H. speciosa*, *H. ovata*, *H. littoralis*, *H. Caribæa*, *H. expansa*, *H. crassifolia* and *H. Galvestonensis*—grow and flower in a living-room as freely as Geraniums. *H. macrostephana* exceeds them all in vigor and in ease of management. The flower-stem, which is thrown up from the heart of the bulb, reached this year the height of seventeen inches, and produced an umbel consisting of seven flowers, each eight and a half inches long, with a cup three inches broad and segments four and a half inches long. Their vanilla-like perfume is so strong that one flower scents a large room and a flowering umbel an entire house. No one seems to know where this species, the best of the genus, comes from. Mr. Baker, of the Kew Herbarium, who has devoted a great deal of attention to the study of these plants, is of opinion that it may prove a hybrid between *H. speciosa* and *H. (Ismene) calathina*. I grow my plant in summer in the open air in a half shady situation, and bury the pot to the rim in coal ashes.

Milwaukee, Wis.

H. Nehrling.

Dendrobium aqueum.—This species has been in cultivation almost fifty years, having been first imported from Bombay in 1842 by Messrs. Loddiges, of Hackney, in whose nurseries it flowered the following year. It extends southward in greater or less quantities along the mountains of the Malabar coast, growing on the trunks of trees and bushes. It is not often, however, that plants are seen in collections, and the reason is difficult to explain, because when well grown *D. aqueum*, or, as it is perhaps more popularly known, *D. album*, presents an attractive appearance. In the beginning of September a fine specimen was exhibited by Mr. T. Statter at the Royal Horticultural Society, and almost every stem bore several white flowers, each one being a half to two inches across, and arranged either singly or in fascicles of two and three. The upper sepal is oblong-acute, the lower ones more or less triangular, while the ovate petals are somewhat broader. The lip is three-lobed, the anterior segment being finely toothed on the margin, and having a downy pubescence on the upper surface,

which is tinged with yellow at the base. The stems, which are more or less decumbent, are from one to two feet long, yellowish green when young and having an oblong-lanceolate, deep green, leathery leaf about three or four inches long at each node.

D. aqueum may be grown equally well in baskets or in pots well drained with clean crocks. The usual compost is rough peat, with a little moss and charcoal added. Plenty of water may be given when the growths begin to develop rapidly, and as much light as possible, without exposing the plants to the direct rays of the sun on very hot days. The temperature in summer during the day-time may range from seventy to eighty degrees Fahr. and a few degrees lower at night, while in winter, when the plants are taking a short rest, a temperature of sixty to seventy degrees Fahr. will be found sufficient until the new growths show signs of breaking.

Isleworth, London, W.

John Weathers.

Hardy Perennials from Seed.—As I have succeeded so much better of late years with seeds of hardy herbaceous plants sown in late fall or winter than when sown in spring, I have determined to sow all the seeds of these plants in November. I shall allow them to freeze and then cover with mats and shutters, and not open them until early spring. I have been led to do this mainly by the uncertain way a large number of species of hardy-plant seeds germinate when sown in spring. Too often we are disposed to say, when seeds fail to come up in six weeks or two months, that the seed is bad; but if we note the straggling way in which many kinds of spring-sown seeds come up all through the ensuing summer, and that many do not germinate in any quantity until the spring following, we cannot help thinking there is a reason. In the case of *Pæonies*, *Hellebores*, *Clematis*, *Cimicifugas*, *Actæas*, perennial *Adonis*, *Thermopsis*, *Petalostemon*, *Baptisias*, some *Pentstemons*, *Liliaceous* plants generally, and *Gentians*, we should conclude that they might better be sown as soon as ripe. These are the worst cases of slow germination; but even in the case of others, which ordinarily come well, I think it better to sow in fall. As it is only by experience that we find just which kinds to sow early in the season, I have decided to wait until freezing weather. *Alyssum saxatile*, *Aubrietias*, *Campanulas*, *Cheiranthus*, *Delphiniums*, *Dianthus*, *Iberis*, *Lychnis*, *Papavers*, *Silenes* and many others if sown before freezing weather would germinate and be lost.

By this plan time is saved. The work of seed sowing in spring is too often deferred, for one reason or another, until well on in March. By that time the sun has attained considerable power, necessitating frequent watering, so detrimental to germinating seeds. I prefer to use square, shallow pans; space is saved, as well as its being easier to divide up the pans for two or four lots of seeds should it be desirable. Ordinary loam, free from manure or other decaying vegetable matter, is best. The finest seeds should not be covered and the larger ones slightly, pressing all down, after sowing, with a brick. Plunge in sand, certainly not in litter or other decaying matter liable to the development of Fungi or the harboring of vermin. There will be no necessity to open, except for inspection, before the middle of February. Then give air every bright day, and we shall be surprised to find how soon seedlings will begin to appear.

A Reserve Garden.—This is a necessity where hardy plants are grown. It may be an experimental garden as well. Odd corners are generally utilized; but a handy square patch, laid out in sections, with water convenient, would be better. Just as soon as any seedlings become large enough to handle they could be pricked off into other pans or shallow boxes, afterward to be transferred to the open ground. It is always a pleasure to know a stock is at hand to fill up gaps in spring. There is no doubt they will occur as long as inexperienced men are employed to "dig up" borders. I have often regretted, through press of other work, having to forego the pleasure of going over the borders myself. I am opposed to digging. An overhauling, or taking of stock, is all that is necessary, except every four or five years, and then trench and replant.

Wellesley, Mass.

T. D. Hatfield.

The Autumn-Bearing Raspberries.—The fact that fruits are most abundant at this season is, perhaps, the reason why Raspberries that fruit in the autumn have not become more popular; and as many amateur fruit-growers may not know that we have varieties of this fruit which bear freely in autumn, I state that a few sorts of the Red Raspberry, under ordinary culture, mature two crops of berries during the season, the first at the usual time for Raspberries, and the second during September and October. The new growth of these varieties commence to bloom late in summer. The fruit from these early

flowers, which are borne near the outer ends of the canes, commences to ripen early in September and continues to mature until checked by hard frosts. A sufficient number of the flower-buds fail to open in the fall to make a fair second crop the following summer. By cutting off the new growth late in autumn or early in the spring the summer crop may be prevented, and a much larger autumn crop is the result. I am now growing a variety called the Erie. At this date (October 9th) it is well laden with fine fruit, and in New York I have gathered ripe fruit from this variety as late as October 25th. Despite the cool weather of the past few weeks the berries have matured rapidly, and are fully equal in flavor to those that ripened on the same bushes in July. The mature fruit remains on the plant much longer in autumn than in summer, and it is not injured by moderate frosts.

It has occurred to me that the autumn Raspberries might have an especial value in northern localities, where the Grape cannot be grown and only the Crab-apple among tree fruits succeeds. By cutting off the stems in autumn the roots could easily be protected during winter, while the flowers coming out at midsummer would not be endangered by frost.

Correspondence.

The American Elm.

To the Editor of GARDEN AND FOREST :

Sir.—The illustration of the Feathered American Elm in GARDEN AND FOREST (p. 467) has an especial interest for me, as it calls to mind several handsome specimens of the same class growing on my father's homestead in southern New York. The tall, columnar trunks of these primeval Elms often rise to the height of fifty feet before dividing into branches, yet from the ground they are clothed with numerous tufts of slender, and often drooping, shoots, which, in summer, give to these noble trees a very unique appearance. These tufts often arise from roundish, knotty protuberances of greater or less size, which give the trunk a rugged and picturesque aspect.

On the same farm, until within a few years, stood another venerable American Elm, which, in habit, was the exact opposite of the ones above described. In place of a lofty, towering trunk, with strongly ascending branches at the summit, this motherly old tree divided, at the height of a man's head, into several massive branches, which extended horizontally a distance of thirty feet or more, and finally broke up into slender, drooping spray that literally reached the ground.

I have often queried if these strikingly different habits might not be perpetuated by grafting. I had formerly supposed that the peculiar forms assumed by these trees were due largely to the influence of other trees that grew up with them and have long since been cut away, but observation of the habits of isolated trees that have largely grown up within my recollection do not require any such explanation. Surely no other native forest-tree has a greater tendency to variation in form than the American Elm.

When left to itself, the American Elm often shows a tendency to develop only two, three or four principal branches, which grow out to a great length and often curve downward more or less at their extremities. When grown as a lawn or road-side tree, this habit is objectionable because it tends to make the head unsymmetrical and poorly furnished with foliage, while the long and slender branches are likely to be broken off by winds.

To prevent this undesirable form it is necessary to watch the growth of the young trees and severely head in the shoots that show a tendency to outstrip their companions. This will secure the formation of a number of principal branches, which not only increase the symmetry of the head and clothe it with dense masses of verdure, but enable it to endure high winds without injury.

University of Wisconsin, Madison.

E. S. Goff.

Three Questions.

To the Editor of GARDEN AND FOREST :

Sir.—I have made several attempts to transplant *Cornus florida*, but I have been unable to get my plants well through the first autumn, and after several attempts I have not one well established specimen. Are they difficult to transplant?

Will you kindly give me a complete list of evergreen trees and shrubs, not conifers, which will endure the winters of this region? Will any of the Magnolias, Andromedas or Rhododendrons endure a temperature which occasionally falls to thirty degrees below zero with bright sunshine following?

What perennial flowering plants are better planted in the fall in this latitude, forty-three north? Is this the best time to plant Pæonies?

Whitewater, Wis.

Albert Salisbury.

[There is no particular difficulty in transplanting *Cornus florida*. As is the case with other trees, nursery-grown plants which have been frequently transplanted, and are therefore furnished with plenty of short fibrous rootlets, are more easily established than plants dug from the woods, which cannot be moved except at the sacrifice of a large part of their roots. For this reason it is always better, when practicable, to obtain plants from a good nursery, even although they are considerably more expensive, than it is to undertake to remove them from the woods.

There is probably no broad-leaved evergreen-tree capable of supporting the climate of Wisconsin and very few evergreen shrubs, whose cultivation there must be largely a matter of experiment. *Rhododendron maximum* grows naturally in a region where the thermometer sometimes falls to thirty degrees below zero, but, like the other plants of its family, it cannot be grown in soil impregnated with lime. The Inkberry, *Ilex glabra*, is an evergreen species which grows on the Atlantic coast as far north as Massachusetts, and it might be expected to endure the climate of Wisconsin. *Euonymus radicans*, a climbing evergreen species from Japan, is perfectly hardy in New England, and it should be tried, if it has not been already, in the north-western states. Probably none of the evergreen Andromedas would grow in Wisconsin, where, however, *Magnolia glauca*, which grows as far north on the Atlantic coast as the Inkberry, might be expected to succeed.

Nearly all strong-growing perennial plants can be divided and replanted in the autumn, but it should be done early enough to enable them to make new roots and become established before the ground freezes up. Probably the best time to transplant Pæonies at the north is early in September, as they start to grow so early, especially those having woody stems, that it is almost impossible to transplant them in the spring before growth commences.—Ed.]

Recent Publications.

Two Years in the French West Indies, by Lafcadio Hearn (Harper & Brothers, New York, 1890), contains a number of sketches of Martinique and of its interesting population, which bring before our eyes "Le Pays des Revenants" more accurately and pleasantly than anything which has yet been printed about the most picturesque of the Lesser Antilles.

A tropical forest is indescribable, perhaps, but one may get at least a vivid impression of it from the following sentences which Mr. Hearn has translated from the writings of Dr. Rufz, a Creole of Martinique, and which, as we read them, bring back to us the days we passed long ago in these forests, and all the strange and awful beauty which surrounded us:

"The sea, the sea alone, because it is the most colossal of earthly spectacles—only the sea can afford us any term of comparison for the attempt to describe a *grand-bois*—but even then one must imagine the sea on a day of storm suddenly immobilized in the expression of its mightiest fury. For the summits of these vast woods repeat all the inequalities of the land they cover; and these inequalities are mountains from 4,200 to 4,800 feet in height and valleys of corresponding profundity. All this is hidden, blended together, smoothed over by verdure, in soft and enormous undulations—in immense billowings of foliage. Only, instead of a blue line at the horizon, you have a green line; instead of flashings of blue, you have flashings of green—and in all the tints, in all the combinations of which green is capable: deep green, light green, yellow green, black green.

"When your eyes grow weary—if it indeed be possible for them to weary—of contemplating the exterior of these tremendous woods, try to penetrate a little into their interior. What an inextricable chaos it is! The sands of a sea are not more closely pressed together than the trees are here: some straight, some curved, some upright, some toppling—fallen, or leaning against one another, or heaped high upon each other. Climbing lianas, which cross from one tree to the other, like ropes passing from mast to mast, help to fill up all the gaps in this treillage; and parasites—not timid parasites like Ivy or like

moss, but parasites which are trees self-grafted upon trees—dominate the primitive trunks, overwhelm them, usurp the place of their foliage, and fall back to the ground, forming factitious Weeping-Willows. You do not find here, as in the great forests of the north, the eternal monotony of Birch and Fir: this is the kingdom of infinite variety—species the most diverse elbow each other, interlace, strangle and devour each other: all ranks and orders are confounded, as in a human mob. The soft and tender *Balisier* opens its parasol of leaves beside the *Gommier*, which is the Cedar of the colonies—you see the *Acomat*, the *Courbaril*, the Mahogany, the *Tendre-à-caillou*, the Ironwood . . . but as well enumerate by name all the soldiers of an army! Our Oak, the Balata, forces the Palm to lengthen itself prodigiously in order to get a few thin beams of sunlight; for it is as difficult here for the poor trees to obtain one glance from this king of the world as for us, subjects of a monarchy, to obtain one look from our monarch. As for the soil, it is needless to think of looking at it: it lies as far below us probably as the bottom of the sea—it disappeared ever so long ago, under the heaping of débris—under a sort of manure that has been accumulating there since the creation: you sink into it as into slime; you walk upon putrified trunks, in a dust that has no name! Here, indeed, it is that one can get some comprehension of what vegetable antiquity signifies—a lurid light (*lurida lux*), greenish, as wan at noon as the light of the moon at midnight, confuses forms and lends them a vague and fantastic aspect; a mephitic humidity exhales from all parts; an odor of death prevails, and a calm, which is not silence (for the ear fancies it can hear the great movement of composition and of decomposition perpetually going on), tends to inspire you with that old mysterious horror which the ancients felt in the primitive forests of Germany and of Gaul:

“ ‘Arboribus suis horror inest.’ ”

The following description of the Botanic Garden at St. Pierre will be read with interest. It is the oldest garden in the West Indies, and certainly one of the most picturesque in situation; and although sadly neglected and overgrown, it contains many tropical trees which cannot be seen in any other garden in America to such advantage:

“The garden is less than a mile from the city, on the slopes of the Morne Parnasse; and the primitive forest itself has been utilized in the formation of it, so that the greater part of the garden is a primitive growth. Nature has accomplished here infinitely more than art of man (though such art has done much to lend the place its charm), and until within a very recent time the result might have been deemed, without exaggeration, one of the wonders of the world.

“A moment after passing the gate you are in twilight, though the sun may be blinding on the white road without. All about you is a green gloaming, up through which you see immense trunks rising. Follow the first path that slopes up on your left as you proceed, if you wish to obtain the best general view of the place in the shortest possible time. As you proceed, the garden on your right deepens more and more into a sort of ravine, on your left rises a sort of foliage-shrouded cliff; and all this in a beautiful crepuscular dimness, made by the foliage of great trees meeting overhead. Palms rooted a hundred feet below you hold their heads a hundred feet above you, yet they can barely reach the light. . . . Farther on the ravine widens to frame in two tiny lakes, dotted with artificial islands, which are miniatures of Martinique, Guadeloupe and Dominica; these are covered with tropical plants, many of which are total strangers even here; they are natives of India, Senegambia, Algeria and the most eastern east. Arborescent Ferns of unfamiliar elegance curve up from path-verge or lake-brink, and the great arbre-du-voyageur outspreads its colossal fan. Giant lianas droop over the way in loops and festoons; tapering green cords, which are creepers descending to take root, hang everywhere, and parasites with stems thick as cables coil about the trees like boas. Trunks shooting up out of sight, into the green wilderness above, display no bark; you cannot guess what sort of trees they are; they are so thickly wrapped in creepers as to seem pillars of leaves. Between you and the sky, where everything is fighting for sun, there is an almost unbroken vault of leaves, a cloudy green confusion, in which nothing particular is distinguishable!”

“It is of another century, this garden; special ordinances were passed concerning it during the French Revolution (An. II.); it is very quaint; it suggests an art spirit as old as Versailles or older; but it is indescribably beautiful even now.

“ . . . At last you near the end, to hear the roar of falling water; there is a break in the vault of green above the bed of a river below you, and at a sudden turn you come in sight of the cascade. Before you is the Morne itself, and against the

burst of descending light you discern a precipice verge. Over it, down one green furrow in its brow, tumbles the rolling foam of a cataract, like falling smoke, to be caught below in a succession of moss-covered basins. The first clear leap of the water is nearly seventy feet. . . . Did Josephine ever rest upon that shadowed bench near by? . . . She knew all these paths by heart; surely they must have haunted her dreams in the after-time!”

“The beautiful garden is now little more than a wreck of what it once was; since the fall of the Empire it has been shamefully abused and neglected. Some agronomer sent out to take charge of it by the Republic began its destruction by cutting down acres of enormous and magnificent trees—including a superb alley of Palms—for the purpose of experimenting with Roses. But the Rose-trees would not be cultivated there, and the serpents avenged the demolition by making the experiment garden unsafe to enter—they always swarm into underbrush and shrubbery after forest-trees have been cleared away. . . . Subsequently, the garden was greatly damaged by storms and torrential rains—the mountain river overflowed, carrying bridges away and demolishing stone work. No attempt was made to repair these destructions; but neglect alone would not have ruined the loveliness of the place—barbarism was necessary! Under the present negro-radical régime orders have been given for the wanton destruction of trees older than the colony itself; and marvels that could not be replaced in a hundred generations were cut down and converted into charcoal for the use of public institutions.”

Part IX. of Forbes & Hemsley's *Enumeration of Chinese Plants*, published in the *Journal of the Linnean Society*, has just appeared, and carries this valuable and important work through the *Plantaginæ*, and includes, besides that family, *Acanthaceæ*, *Verbenaceæ* and *Labiataæ*. Two new genera, *Loxocalyx* and *Hancea*, are proposed by Mr. Hemsley. The first is a herbaceous plant discovered by Henry in the Hupch district. It is remarkable in the elongated lower lip of the calyx, and in the very long stalk of the ovary, which is as long or longer than the ripe nutlets. *Loxocalyx* is placed provisionally near *Otostegia* and *Roylea*; a figure of the only species, *L. urticifolius*, is given. There is a figure, too, of *Hancea Sinensis*, the type of a genus detected by Faber on Mt. Omei, and which, Mr. Hemsley points out, resembles in habit, foliage and axillary racemose inflorescence the Japanese genus *Keiskea*, while in floral characters it approaches very nearly to *Gomphostemma*. The genus is dedicated to the memory of the late Dr. Hance, whose investigations into Chinese botany during a long residence at Hong-Kong are well known. The present part contains descriptions of a large number of new species, principally the discoveries of Henry and Faber.

Notes.

A train of ten cars loaded with Lima beans left Ventura County, California, for the east last week.

Mr. Charles Howard Shinn has been appointed Director of the Agricultural Experiment Station in California.

The *Bulletin d'Arboriculture* says that an excellent way to propagate *Hydrangea paniculata* is by means of flower-buds. These should be taken off with a heel when they root readily, and the method is especially useful if it is desired to force small plants quickly into flower for use in the house.

The *Gardeners' Magazine* makes mention of the fact that there is a white *Vallota* in existence. The stock is in the hands of Mr. Thomas S. Ware, of the Hale Farm Nurseries, Tottenham, London, England, who is preparing it for distribution. It will be a valuable addition to our garden plants if possessed of the good qualities which render *V. purpurea* so conspicuous.

A correspondent sends us some unusually fine fruits of the east Asian Orange, *Citrus trifoliata*, ripened in the open air in the Zoological Garden at Philadelphia. These plants, which are said to have been raised from seed collected in Palestine—of course, in a garden—have produced fruit for a number of years. They are in flower early in August, and the fruit is ripe two months later.

Le Moniteur D'Horticulture, quoting from *Le Journal des Campagnes*, describes the process used by French confectioners to reproduce artificially the flavor of strawberries in bonbons and ices. Chemistry, it seems, is able to imitate not only the taste but the perfume of the strawberry in all its delicacy by a combination of butyrate of ethyl, five parts; nitric ether, one part; formiate of ethyl, one part; acetate of ethyl,

four parts; salicylate of methyl, one part. The extract is said to be entirely harmless.

Mr. Sereno Watson continues his Contributions to American Botany, printed in the *Proceedings of the American Academy of Arts and Sciences*, No. 17 of the series having been issued on the 25th of September. It contains miscellaneous notes upon North American plants, with descriptions of a number of new species, and descriptions of new species from northern Mexico, collected principally by Mr. C. G. Pringle in 1888 and 1889. A number of new species and three new genera discovered by Mr. Pringle are here characterized.

The "Adirondack League Club," which owns 93,000 acres of forest-land, is at once to have its property carefully surveyed and inspected under the direction of Mr. B. E. Fernow, Chief of the Forestry Bureau of the Department of Agriculture at Washington, its desire being to preserve and administer its forests in the most scientific way. The example thus set to other owners of woodlands cannot be too highly approved. Nor has the aid of an expert in this special case been sought too soon, if it is true that the club has signed a contract to sell annually for the next fifteen years \$30,000 worth of ripe Spruce timber.

The Manchurian representative of the Tartarian Maple (*Acer Tartaricum*, var. *Ginnala*) is not surpassed by any plant in the beauty of the coloring of its autumn foliage. The leaves appear earlier than those of the native Maples, with the exception of the Red Maple, and assume the most brilliant scarlet tints imaginable, retaining the color for a long time. This Maple has proved one of the most valuable of all small exotic trees for our northern gardens. It is very hardy; the habit is good, and the flowers, an unusual thing in flowers of the Maple, possess a delightful fragrance. It was introduced several years ago into the Arnold Arboretum from St. Petersburg. The largest plants in this country are now eighteen or twenty feet high, and flower and fruit regularly every year.

At a recent meeting of the Geographical Society of Germany, Chief Forest-master Kessler spoke strongly of the waste and recklessness to which the forests of the United States are falling a prey. Even now, as he pointed out, only eleven per cent. of the surface of this country is in forest, as against twenty-six per cent. of the surface of Germany. As our population increases the proportion of wood supply to our needs will, of course, rapidly diminish, but already the destruction of our woodlands menaces not only the revenues which might forever be derived from them, but also the fertility of the soil in many broad districts. It is encouraging to learn that Mr. Merritt, our Consul at Chemnitz, in Saxony, drew the attention of our Government to Herr Kessler's remarks in a recent official report.

In his "Year Among the Trees; or, Woods and By-ways of New England," published about ten years ago, Mr. Wilson Flagg says: "When I am journeying through the country and behold the rocky hills, sometimes for miles in extent, entirely bare of trees and affording too little sustenance to support even a crop of Whortleberry-bushes, where an acre would hardly pasture a single sheep, I am informed by the older inhabitants that these barren fields were since their childhood covered with forest. This wood cannot be restored, because the soil has been washed down from the surface to the plains below, and nothing remains to support a new growth of trees. And then I think, if our predecessors, instead of wrangling about theology, had left its mysteries to be explained by their pastors, and had studied some of the plain laws of meteorology, this devastation had not taken place." Even to-day, we may add, few persons realize that the laws of meteorology, as well as of forestry itself and of commercial conditions, insistently proclaim the necessity of forest-preservation.

Under the McKinley bill a duty of twenty per cent. ad valorem is now levied on "plants, trees, shrubs and vines of all kinds known as nursery-stock" imported into the United States. They were formerly admitted free. "Orchids, Lilies-of-the-Valley, Azaleas, Palms and other plants used for forcing under glass for cut flowers or decorative purposes" are still retained on the free list, and bulbs or bulbous roots not edible, on which a duty of twenty per cent. was levied under the old law, are now placed on the free list. Garden and agricultural seeds, and other seeds not specially provided for, with a few exceptions, still pay twenty per cent. ad valorem, although the following are on the free list: Anise, Canary, Caraway, Cardamom, Coriander, Cotton, Cummin, Fennel, Fenugreek, Hemp, Hoarhound, Mustard, Rape, St. John's Bread or Bean, Sugar-beet, Mangel-wurzel, Sorghum or Sugar-cane for seed, and all flower or grass seeds. These changes are likely to make a

very considerable difference in the horticultural business of the country. The admission of bulbs of flowering plants free of duty should largely increase the importations of these plants and stimulate their cultivation in this country. The duty of twenty per cent. on so-called nursery-stock is likely to have unfortunate results. Some plants, like hardy Rhododendrons, hardy Azaleas, and certain conifers which require special climatic conditions and much skilled labor to produce to the best advantage, cannot be well grown in this country, and the duty must have the tendency of reducing the number of such plants used here. The retention of the duty on greenhouse plants, which, so far as their production goes, come under the same category as the plants already mentioned, is due to special efforts of the florists of the country. The duty will not affect, probably, the production of forest-tree seedlings in this country, and the only result will be to increase the cost to the planter. American nurserymen have already demonstrated their ability to produce better plants of this class at less cost than they can be imported for from any European country. The trade in Roses will probably be benefited by the duty, as it has been the habit of some Continental growers to glut this market yearly with their surplus and generally badly grown stock, which under forced auction sales has demoralized prices and made it difficult to find a market at fair prices for good plants grown in this country or in England.

An interesting bulletin from the Experiment Station of the Kansas State Agricultural College treats of *Experiments with Fungicides for Stinking-Smut of Wheat*. In many localities, in nearly every Wheat-growing country, the crop is more or less injured by this disease. It is not detected until the plants have headed out, and even then it is often overlooked. Before the grain ripens a careful examination shows that certain heads have a dark, bluish green color, while healthy plants present a lighter, yellowish green color. During and after ripening of the grain the smutted heads have a paler appearance than healthy ones. At no time do the smutted heads present the yellowish shade so characteristic of ripening Wheat. When the smutted heads are examined it is found that the grains have become dark and more or less swollen. They are at first of a greenish color, but become brownish or grayish when fully ripened. Because of their being usually swollen, the smutted grains push the chaff apart more than the sound kernels do, giving the head a slightly inflated appearance. If one of the swollen smutted grains be crushed it is found to be filled with a brownish powder which has a very disagreeable and penetrating odor. Often the disease is not discovered till the grain is threshed, when it is recognized by the odor from the smutted grains crushed by the machine. The smut may also be recognized during the milling, both from the odor arising during the grinding and by the dark streaks found in the flour. The dissemination of the disease is brought about by the use of smutted seed. The brown powder lodged in the threshing-machine may infect the seed, or the smut remaining in the field may, perhaps, through the soil, infect the succeeding crop. A summary of the results of the experiments at the Kansas Station, which were carried out by the botanists W. A. Kellerman and W. T. Swingle, shows that the stinking-smut of Wheat is caused by two closely allied parasitic Fungi called *Tilletia foetens* and *Tilletia Tritici*; that these two species of smut differ only in a few microscopic characters, and both produce the same disease, which is spread by spores adhering to the sound grains before they are planted, or, perhaps, rarely by spores present in the soil; that the damage from this disease is often very considerable, sometimes amounting to from one-half to three-quarters of the whole crop; that in ordinary cases the disease can be entirely prevented by soaking the seed fifteen minutes in water heated to 132° F.; that the other fungicides used, when decreasing the amount of smut, at the same time also interfered with the germination, and reduced the vigor of the plants, and that seed from clean fields (if the adjoining fields were not smutty) will produce a crop of Wheat free from smut.

Catalogues Received.

GLENN & DRAKE, Columbus, Ind.; Fruit and Flower Seeds and Bulbs.—HAAGE & SCHMIDT, Erfurt, Germany; Novelties of Seeds and Bulbs.—FRED. W. KELSEY, 145 Broadway, New York; Trees, Shrubs, Roses, Bulbs and Hardy Plants.—SPRING CITY NURSERIES COMPANY, Huntsville, Ala.; Fruit and Ornamental Trees.—SAMUEL C. MOON, Morrisville Pa.; Ornamental Trees and Plants, Fruits, etc.—SCHLEGEL & FOTTLER, 26 South Market Street, Boston, Mass.; Seeds, Bulbs, Roots, etc.—JAS. M. THORBURN & CO., Fruit, Vegetable and Flower Seeds.—THOS. S. WARE, Tottenham, London, England; Tree and Herbaceous Pæonies.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE : TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, OCTOBER 29, 1890.

The Improvement of Trees.

IMMENSE progress has been made, certainly, in the last two hundred years in collecting facts about the trees of the world and their utility to man, and much has been done toward determining the best methods for their cultivation and something for their improvement. There is still, however, much work of practical value to be accomplished by the scientific dendrologist, whether his investigations are directed to the improvement of forests or to the study of trees from the gardener's point of view.

Trees useful primarily for the production of timber require long years, some of them centuries, in which to complete the cycle of their existence. The observer who records his investigations on the seedling Oak or Pine cannot hope to do more than see the seedling become a vigorous young tree. Then another man must take up the investigation where the first dropped it, and so on from generation to generation of men until the tree has lived out its long existence. The difficulty of careful and sustained observations made on growing plants increases immensely as their period of individual life is lengthened; a man who is ready to undertake the most minute and difficult investigations in plant life whenever he feels that there is a chance of his reaping a reward during his own life, hesitates naturally when he knows that his work can only be finished, if finished at all, by unknown hands. This, perhaps, is the reason why fruits and vegetables and flowers have been improved by selection and hybridization, and why the selection of individual trees to be grown for timber is still left largely to chance.

It can hardly be doubted, however, that trees, whether grown for timber or for ornament, can be improved by methods similar to those which have been used for the development of our modern fruits and vegetables, and that the time must come when the same attention will be paid by scientific foresters to the improvement of races of timber-trees as is now paid to the improvement of plants of far less importance to the human race.

There are certain individuals of every species of plants which, for some reason or other, grow more vigorously

than others or possess other exceptional qualities. This fact has been taken advantage of to establish new races of garden-plants, but in the case of trees it has been too generally overlooked, and sufficient attention has never been paid to the selection of the seed-bearing parents, the mothers of future forests. The whole question of the improvement of trees, whether as producers of timber or merely as ornaments of gardens and parks, is still before us. Humbler plants often gain hardness by the mingling of the blood of allied species, and what little has been learned of the few natural hybrid trees known to exist shows plainly that it is within the bounds of possibility to produce trees artificially by hybridization which may possess certain qualities to a greater degree than either of their parents. Then there is the whole question of the relation of the stock to the graft as applied to the production of timber-trees to be investigated. It is known that certain trees, when it is desirable to produce them under certain conditions, grow much more rapidly and vigorously, while young at least, if they are grafted, than they do on their own roots; but time and careful observations are needed to determine what results, from economical points of view, will finally be obtained by such a method of propagation.

All such questions as these are matters which must one day occupy the attention of scientific foresters, and which can only be solved at well equipped forest-stations, which all governments, following the example of Germany, can wisely establish; for without the stability which governments alone can give, scientific observations, demanding a longer period than the life of one generation of men, are apt to be barren of useful fruit.

Such thoughts naturally lead us to consider whether it is not possible to increase the number of ornamental trees to be grown in any particular region and the beauty of individuals by the application of the same rules of selection of seed from exceptionally fine individuals as we now employ in producing cabbages or radishes. This seems such an evident proposition that it requires no argument to support it; and yet how few persons who raise trees from seeds pay the slightest attention to the character or health of the individual which supplies them. For the ordinary collector of tree-seeds in the nursery or the forest a seed is a seed, and the fact is ignored or forgotten that the constitutional weakness of an individual plant can be transmitted through its seed. Neglect to properly select the seed-parent is doubtless the cause why many nursery-grown trees fail before their time, and why seedlings raised from trees subjected in cultivation to more or less unnatural conditions are less desirable than those raised from individuals growing spontaneously under the most favorable natural conditions.

The possibilities of tree-culture widen when it is considered that there are certain species which possess a much greater power than others of adapting themselves to their surroundings—that is, which possess greater constitutional flexibility. Such species are able to exist over wide areas through individuals being able to support greatly diversified climatic conditions. If this fact is taken advantage of and trees for any particular region are raised from seed grown in a climate as similar as possible to that where the seedlings are to be planted, these may be expected to adapt themselves to their new surroundings more readily than if the seed-parent had grown in a less favorable locality. This is shown by the familiar instance of the Douglas Spruce. This tree is widely distributed in western America from British Columbia to Mexico, and eastward to the eastern base of the Rocky Mountains. It was first made known from the neighborhood of Puget Sound, where the climate is mild and humid. Plants raised from seed collected there grow well in England, where the climate is not dissimilar to that of our north-west coast; but when these plants were brought from England to our eastern states they failed entirely. Many years later this tree was found in the Rocky Mountains in a severe climate, and seeds from the Colorado trees were planted in New England, and have proved abundantly hardy and in every way

satisfactory. This is true, too, of another widely distributed western tree, *Abies concolor*, which is hardy in the east when grown from seed gathered in Colorado, but only precariously hardy when the seed-parents have grown in the milder climate of the California Sierras; and it is doubtless true of all trees which have a wide north and south distribution or which grow from the sea-level up to high elevations. *Magnolia glauca* grows from Massachusetts to Florida and Texas; it is as hardy at the north as at the south, and yet no one can doubt that seedlings of this tree raised from seed gathered in Florida would produce plants which would succumb in Massachusetts during their first winter.

The study of trees with relation to their distribution and the peculiar conditions with which certain individuals of the species are surrounded is full of possibilities, and promises to greatly increase the material which can be grown in regions of severe climate. Professor Budd has already shown, by means of the useful experiments with Russian and central Asia plants which he has been carrying on in Iowa for a number of years, that individuals of many species vary remarkably in their power to adapt themselves to severe climatic conditions; and the work which has already been done in this direction can be greatly extended in the case of many of our own southern trees, which can probably be cultivated further north than is now believed possible through the selection of seeds from individuals grown at the extreme northern point of the natural distribution of the species. This is true, too, of the trees of Japan and China, where many species range north and south through as many degrees of latitude as separate Massachusetts from Florida. Many of these Asiatic trees, as we know them here in cultivation, fail because they have not always been derived from the best regions so far as climate is concerned. Even European trees, which Americans have usually obtained from England, have not always had a fair trial here, and which, had their seed-parents been selected from regions of colder or drier climate, might possibly have been able to adapt themselves to ours. We may even obtain a Cedar of Lebanon, the ambition of most American tree-planters, which will flourish in the extreme northern states, if some one will take the pains to obtain seeds from the right place. The old Cedars of England came originally from the famous grove on Mount Lebanon, which is near the southern limit of the area occupied by the species, and the plants which we have tried in this country, and which have failed with us, were raised from these English trees or from seeds gathered on the Lebanon. But in recent years the range of the species has been extended, and now it is known that this tree forms extensive forests on higher and more northern mountains than the Lebanon, in a region which furnishes trees like the Cilician Fir, which flourishes in New England better than most Firs. It is evident, therefore, that if we are ever to have a Cedar of Lebanon experiments must be made with seed gathered at the northern limit of its range; and what is possible of the Cedar of Lebanon is possible, perhaps, of the Cedar of the Himalaya and of a hundred other trees which could be mentioned, and which we consider unsatisfactory here because they have never had the best trial possible with reference to our climate.

It is by making such experiments as these that arboreta, botanic gardens and our agricultural experiment stations can do practical and useful work.

Alphonse Karr.

ALPHONSE KARR, who recently died at Nice in his eighty-third year, was the son of a German musician, but was in heart and soul a child of the Paris where he was born. Not an act of his varied life seems to have shown, and not a line he wrote reveals, the presence of Teutonic blood. There is no need to explain the purely Gallic character of the novels which early made him famous. Even their sentimentality, though it seems alien to the France of to-day, is of the sort which characterized the France, not the Germany, of two generations

ago. Nothing could speak less of a Teutonic spirit than the fact that he edited the *Figaro* for a time and established it upon the lines it still follows to-day. Purely Gallic, too, is the quality of his style—graceful, light, brilliant, digressive, shot with that kind of wit which is biting yet never bitter, and, whether sarcasm or sentiment is its theme, never passing the bounds of literary good taste. I cannot discover his mother's name, but she must surely have been a Parisian and he must surely have been her very own.

Even in his early books signs appear of that love for Nature which led him to adopt horticulture as a profession, when, disgusted with Paris after the revolution of 1848, he established himself at Nice. But it was three years before this date that he published the "*Voyage autour de mon jardin*," which is likely to outlive any of his other books, and the memoirs which he afterward wrote, under the title of "*Livre de bord*," relate only to his Parisian experiences. So there are no data from his own pen, except in the numerous articles he contributed to garden periodicals, from which an account of his practical horticultural experiences might be gathered.

However, this does not seem to be a matter of great regret, for the cast of his mind was not scientific, so it is doubtful whether much that is definitely instructive would have marked a chronicle of his later years, and the very best that he could have given us in the way of sentimental, poetic and half-humorous writing about plants is surely embalmed in his charming "*Voyage*." No one but a Frenchman could have written this book, and no one should read it who cannot appreciate the quality of Gallic wit and humor, and see the difference between their statements and those of sober, common-sense intelligence. But for persons who can grasp his point of view, even if they stand among the ranks of the scientific men or of the narrow, impassioned horticulturists whom he satirizes with equal gusto, the "*Voyage*" is most delightful reading. They realize, as one reviewer has already said, that when Karr makes fun at the expense of botanists it is as Molière made fun of doctors; and will believe that, as Molière probably was quick to call in a doctor when he needed him, so Karr really appreciated the debt the world owes to science, and even to scientific terminology, the red rag at which he tilts with most delight. Gay humor infuses every satirical line that he writes; when his words take a serious turn it is to praise the works of God, not to castigate the follies of man.

His "*Voyage Around My Garden*" was inspired, he tells us, by envy of a friend who was starting off on a long journey; and it is cast in the form of letters to this friend, begun when he first realized, looking out on his little domain, how easily and agreeably he could travel there, and prolonged until he works himself into a state of contempt for those who choose to go farther and fare worse. There is neither continuity nor system to these letters, and they touch on a thousand topics suggested by something in the garden, but in no sense really connected therewith. The first describes a magnificent sunset, the second a battle between spiders on the garden wall, and the next the superiority of a turf-carpet over the products of even oriental looms, while the fourth passes from birds to Marie Antoinette and Danton. Insects and savants, the difference between formal and genuine ownership in the works of Nature, the true meaning of happiness, the folly of liking tobacco (pointed by an acknowledgment of his own love for the "poison"), fables and anecdotes with flowers or lovers of flowers for their heroes, enthusiastic rhapsodies over one favorite plant or another, and jovial tales of the follies of eccentric amateurs—these are but a few of the themes he treats with infallible delicacy of thought and expression, and with equal charm whether serious sentiment or sarcastic fun-making be his mood. In one chapter he tells us how we live in the midst of death—surrounded by dead vegetable matter, feeding on dead animals, and made comfortable and happy by the hands of long-past generations; in another he describes how his garden was ravaged by an unwelcome guest with a gun and a frantic dog, and it is hard to say which is the more attractive. One day he follows the course of the seasons by recounting how they change his little garden; another time he shows how its aspect varies during the course of twenty-four hours. Now he lies on his back in the grass and reports what he sees; then he turns over on his face and continues the chronicle. A delightful chapter tells how we might have accurate names for all the shades in the long scale of colors if we would only study common flowers and draw our terms from them. Here he tells of an old-time lover of Pinks who grew them in ivory boxes and fastened them to ebony sticks with rings of silver; there we have the history of a man who lost his fortune of 300,000 francs, as well as his peace of mind, all because a friend had seen fit to present him with

twelve Tulip-bulbs of no particular value; and again, *apropos* of the story that when Jove turned Io into a heifer he invented the Violet that she might have suitable food, he declares his intention of making a lawn exclusively of Violets. The sparkling persiflage which is the salt of the book is not spent on scientific men and Tulip-growers only; the poets come in for their share. While botanists have made flowers dull and tedious and florists have made them ridiculous, poets have vulgarized their beauty and distorted their sentiment by the constant repetition of trivial or misleading phrases. The Greeks, he declares, said five or six pretty things about the Rose; the Romans translated these and added three or four more; and later poets of all times and lands have repeated them all, without adding anything fresh, until we are bored to death by their reiteration. Equally tiresome and more foolish is the way poets introduce the name of a flower simply because it gives them an easy rhyme. How often, for instance, do they speak of the *Gladiolus*, simply because it rhymes with the Linden (*glaioul* and *tilleul*), making the flower, most often, grow beneath the tree where no human eye has ever seen it. He gets quite excited over the traditional but wholly fictitious love of the butterfly for the Rose, and nothing could be more amusing than the grave way in which he demonstrates that the Violet is anything but "modest," as poets invariably assert. But to give a sample of everything the "Voyage" contains would simply be to translate the book. Suffice it to add that, while we can gather from it no facts of genuine horticultural importance (it really contains more facts about insects than about flowers), now and then we come upon a stray word which shows the difference between his time and ours. Madame Hardy was then a novelty among Roses; yellow Poppies, he says, were as impossible to find as green or blue ones, and he had never seen a red one streaked with white; he pronounces green Roses a foolish fiction, and says that, despite the great beauty of Pæonies, they are despised by horticulturists and the rich, and grow only in poor folks' gardens. In short, it is a book to charm the lover of Nature in a general way and the lover of graceful and brilliant writing—not a volume for serious students. What we admire most as we close it is "the exquisite delicacy of the senses," which he does not hesitate to boast about himself, and the easy mastery of word and phrase which shows on every page.

The *Livre de bord* is also delightful in its way, which is distinctly anecdotal. And here, too, we occasionally get brief glimpses of his passionate love of flowers. He tells us in one place that before he left Paris he came very near engaging to write a large horticultural dictionary "on a novel plan." He could not have helped making it charming, but we may well doubt whether the world is much poorer in knowledge through its abandonment. In another place he relates how he once formed a "Romancer's Garden" by collecting the queer references to plants and flowers which he chanced upon in the writings of his day. In it he planted a blue Carnation, discovered by Janin; a Chrysanthemum, likewise blue, which George Sand had possessed; a Camellia "of intoxicating perfume," invented by Rolle; a black Tulip belonging to Dumas, a climbing Azalea for which Balzac was responsible, and very many flowers which had bloomed out of season in the grounds of Eugène Sue and other romancers. It was for the compiling of catalogues of this sort, not of prosaic dictionaries, that Alphonse Karr was born. Yet he seems to have known how to grow plants so as to please the buying public as well as to delight himself, and we are glad to think of him spending his long last years—fully half his patriarchal life—solely occupied in gardens under the delicious sky of Riviera.

New York.

M. G. Van Rensselaer.

Max Leichtlin's Garden.

IT is twelve years since I first visited the far-famed garden of Herr Max Leichtlin, at Baden, and though I have more than once attempted to describe it in the *Gardeners' Chronicle* there is always something new to be said. Within a few years it has been increased in size, but it is still far too small to contain the fine plants and bulbs which are brought together from all parts of the world through the skill, liberality and ardor of its owner. There must be something in the climate of Baden which is very favorable; for, although in winter the frost and snow are quite as severe, or even moreso, than in the midland counties of England, and in summer the heat is usually greater, plants from such varied localities as Asia Minor, South Africa, Chili, Sikkim and California all seem to succeed equally well. This, in some instances, is no doubt due to the special provision

made for their culture, and in others to the fresh soil which is frequently renewed in the numerous frames and beds.

Any one who has cultivated a large number of small bulbous plants in close proximity to each other knows how hard it is to keep them from becoming intermixed and to find room in suitable positions for the accessions which are constantly coming in. Herr Leichtlin has always been, and is now more than ever, an advocate for rigid selection, and he will grow nothing that is weedy, of bad habit, or easily increased by ordinary cultivators, but devotes his attention as a propagator and a hybridizer only to such plants as are new, rare or difficult to manage. He annually throws away many plants which would be highly prized by less intelligent collectors. But he never forgets a really good plant, and spares no effort to secure and prove the value of every species in any genus for which he has a special liking.

The practical experience of Herr Leichtlin during thirty years of gardening would make a work of interest and value to the botanist as well as to the gardener. This is specially true with regard to hardy plants. The feature of his garden at this time are Irises, which he has lately introduced from Asia Minor. Though but a few of these plants were still in flower on the 17th of May, they were worth a journey to see. The first plant which attracted my attention on entering the garden was a good specimen of *Ferula Narthex* in full flower. This has been sixteen years in attaining sufficient strength to bloom, and though not a showy plant, it is a very striking one. The branches when broken exude a white sap which produces the drug known as assafœtida, and which, though so unpleasant in its smell, is, when judiciously used by a skilled cook, an agreeable and valuable ingredient in many dishes. The next wonder was *Iris Lorteti*, a very rare and splendid species allied to *I. Susiana*, but much more beautiful in color, and seemingly difficult to cultivate. *Iris Gatesii*, from Asia Minor, is of the same section, but even finer, and seems much more amenable to cultivation. It was sent out for the first time this summer. *Iris lupina* and *Iris paradoxa* are two species rivaling *Masdevallia Chimera* in beauty of structure and delicate, though not showy, coloring. Long beds of *I. Bakeriana*, *I. Bornmulleri*, which is supposed to be the same as *I. Danfordia*, *I. Persica purpurea* and several others, though now long past bloom, and in many instances ripening seed freely, must have been a splendid sight in the winter, when they braved the snow and frost with impunity. Fine varieties of *I. Korolkowi*, *I. Iberica* and many others were either flowering or just about to flower, and quantities of labels without names showed that many surprises are in store.

Herr Leichtlin, like all good bulb-growers, takes up annually almost all bulbous and tuberous rooted plants which have not some special peculiarity; he also puts glasses or lights over many things in order to ripen them more thoroughly and to protect them from the frequent thunder storms which prevail in this valley. The collection of Nerines and Kniphofias is quite unrivaled, and many seedlings are being raised both from selected plants of the best species in these genera and from crosses made between species which appeared capable of improvement in color or habit. It is delightful to see that however small, insignificant or difficult to manage a plant may be, every care is given it, provided it belongs to a good genus or has anything to recommend it. Many plants which have been lost almost everywhere, are to be found here awaiting the discovery either of the secret of their propagation or the introduction of something better of the same character. Among other beautiful or curious plants which I saw were *Jankaea Heldreichii*, allied to *Ramondia* and one of the rarest of European alpine, which had been procured with great difficulty from Mount Olympus in Thessaly; *Geranium Balkanum*, with fragrant leaves and pretty, deep rose colored flowers freely produced; *Onosma albo-roseum*, with hoary, grayish leaves, and numbers of flowers, which are white when first opened, but change to rose color afterward; *Gladiolus Kotschyannus*, a fine hardy species, quite unique in color; a wonderful double Tree Pæony of a deep lake; a very fine white *Aquilegia*, *A. Californica alba*, which, though self-sown, was flowering beautifully in the chinks of the large stones with which the narrow terraces are faced. This system of terracing, very similar to that adopted by vine-growers on rocky hill-sides, is calculated not only to combine depth of soil with thorough drainage, but to accumulate and store up all the sun heat possible. It may not be so picturesque as the ordinary English rock-garden, but for growing many plants which will not thrive in a flat border it is more effective; the species are much more easy to keep separate than when they are divided only by small pieces of rock or stones. I observed a small covered jar placed beside the plants, the seed of which was ripening; this was

intended to attract the attention of the gardener as he might pass and remind him to gather the seed as fast as it ripens without bringing it in-doors. Herr Leichtlin complains, with justice, of the practice in many botanic gardens of keeping valuable seeds for months before distributing them. It is well known that many seeds if not sown in autumn, or as soon after they are ripe as possible, will either not germinate at all or not until from one to two years after planting, long before which time the pots or pans in which they are sown are covered with moss.

If Himalayan collectors, especially, would remember this, we would not have to lament the repeated failure to grow such fine plants as *Primula Elwesiana* and *Gentiana stylophora*, which at present are two of Herr Leichtlin's special desiderata. I found that though he may not be able or even willing to imitate the natural conditions of plants, he is always desirous of knowing as much as possible of these conditions. And he agrees with me that a knowledge of physical geography in connection with plant distribution is highly useful. It is a curious and a gratifying fact that Herr Leichtlin seems to have more correspondents, and to find more gardeners of congenial tastes in England and in the United States than in his own country. I would advise any one who may have a really fine, new or rare and possibly hardy plant which he cannot propagate, to send it to him.

Preston, Cirencester, England.

H. J. Elwes.

October in the Pines.

NO frost has yet touched the Pines, and the flowers and foliage were never more beautiful than now. The ripened leaves of many shrubs and trees are as handsome as gaily colored blossoms. The flowers linger, many summer-blooming plants throwing up side shoots from the old stems.

In my wild garden, where I am trying to imitate Nature in the Pines, blue Violets are in blossom, and so is *Oxalis violacea*, as if trying to blend spring with autumn. Most of the Golden-rods have faded, but *Chrysopsis Marianna* is still beautiful, and some of the wild Sunflowers are a mass of bloom. The wild Asters are charming. *Aster Nova Anglia* is in its prime. In a damp spot in the Pines I came across a variety with rose-colored flowers which were more beautiful and showy than those of the normal purple color.

The water in the shallow, muddy ponds and bogs is still warm enough to keep the Pond Lilies in bloom. But there are no flowers on any other water plants except *Utricularia*.

The foliage of the rare local *Helonia bullata* is beautiful now. Parting the thick clump of glossy, shining leaves, I find the embryo flower-buds. Last spring there were no blossoms. Owing to the mildness of the winter the flower-stems started up in February and March and were cut down by frost. The leaves are evergreen, and grow in a thick mat, as if to protect the incipient flower-buds; but the flower-stem is very tender, and as it is sure to push up on the first mild days of spring it is almost as sure to be nipped by frost.

The foliage of the Sweet Gum (*Liquidambar*) makes a fine appearance during these mild October days. Some of the trees are of a purple shade of color—deep, dark purple on the upper surface of the leaves, but on the under side still green. Others have yellow leaves; but the larger proportion of the trees have red leaves, in varying degrees of intensity of color. I have noticed year after year that each tree always takes on the same color. For instance, if it is yellow one year, we may be sure that it will be the same ever after.

But the charm of the Pines at this season is the Tupelo (*Nyssa aquatica*). Its bright crimson foliage and its peculiar habit of growth—flat, spray-like branches—make it pre-eminently the queen of the region. It does not take kindly to transplanting. I have made several attempts to have small young trees transferred to my garden, but they have all died, some quickly, others gradually. But the tree is worth many more trials, and I still hope for final success.

The next best thing in this latitude in the way of autumnal coloring is the *Sassafras*, which is a rapid grower. Like the *Liquidambar*, the trees vary in tints—some take on yellow, others red. A group of a dozen or more in my garden are now all ablaze in bright orange-red.

The deep green Hollies mingling with these bright colors make charming pictures. There are places here and there in the Pines of such wonderful beauty at this season that no words can do them justice. Less than thirty years ago this town, with all its outlying farms, was covered with a growth of some of the most beautiful trees and shrubs. These were all cut down, and attempts made to grow ornamental trees from the nurseries, many of which are a complete failure. Vineland is a standing proof of the blindness of our people to

true artistic surroundings. From the teachings of GARDEN AND FOREST the more cultured class are beginning to see the mistake; but many of these trees, like the Oaks, and especially the Holly, are of such slow growth that our impatient people, who want quick results, are deterred from replanting.

On the place which I now occupy, several Hollies were planted twenty-five years ago. The largest is less than fifteen feet in height, about twelve feet across the lower branches, and fifteen inches in girth. The trees had not been cared for and had been badly mutilated. The lower branches had been trimmed off four and five feet from the ground, and many of the remaining branches had been broken for winter decorations. A near neighbor planted a Holly-tree about the same time that these were set, and this one tree is worth more than my seven. Its branches touch the ground, and it has been headed back just enough to make it symmetrical without giving it a stiff appearance. It measures nineteen inches in girth, and is about eighteen feet high and fifteen feet broad. It is far more beautiful and effective than a group of Norway Spruces which stand a little distance from it.

Vineland, N. J.

Mary Treat.

New or Little Known Plants.

Two American St. Johnsworts.

THE genus *Hypericum* contains a number of shrubby North American species of considerable value as garden-plants. They are little known, however, to gardeners, and a few, at least, have probably never been cultivated. All the plants of this genus have bright and abundant golden yellow flowers, and the fact that they bloom in midsummer or in early autumn when other shrubs are not in flower, and that they continue to produce their flowers in succession during several weeks, adds to their interest and value. *H. aureum*, of which a figure was published in this journal (vol. ii., p. 185), is a small ornamental shrub of the first class from an ornamental point of view, which was introduced into gardens a few years ago through the Arnold Arboretum. *H. Kalmianum*, figured on page 112 of the present volume of GARDEN AND FOREST, is an older inhabitant of gardens. It was discovered on the banks of the Niagara River, one of the few stations where it is known to occur, by the Swedish traveler Kalm, who visited America about the middle of the last century; and it is 130 years since it was first cultivated in England. Like many of the plants of the eastern part of this continent, which were much sought after and valued by gardeners 100 years ago, it was afterward neglected with a change of fashion in gardening, and finally forgotten outside the limits of a few botanic gardens. It is getting to be understood, however, now that some of the most beautiful trees and shrubs belong to our eastern flora, and that they are the safest and therefore the most desirable plants to use in this part of the country; and American *Hypericums*, like the *Viburnums*, *Dogwoods*, *Roses* and other eastern American shrubs, now seem destined to gain the place in American gardens to which their hardiness and beauty entitle them.

Figures of two of the shrubby *Hypericums* appear in this issue, *H. prolificum* and *H. densiflorum*, and it is proposed to figure from time to time such of the other little known species as are likely to prove desirable as garden-plants.

*H. prolificum** (Fig. 66) is a stout, bushy plant growing to a height of three or four feet by as much in diameter, with stout erect stems and branches covered with light red-brown bark separating readily into thin scales, and slender two-angled branchlets. The leaves are nearly oblong, obtuse or acute at the apex, terminated by a minute mucro, and narrowed at the base. The numerous flowers, which are often an inch and a half across, are produced in great profusion in single or compound terminal clusters. They open in succession and continue to appear almost continually from July to September.

H. prolificum is not a rare plant, and is widely and quite generally distributed from New Jersey to Minnesota and

* *Hypericum prolificum*, Linnæus, "Mant.," 106.—De Candolle, "Prodr.," i., 547.—Coulter, *Bot. Gazette*, xi., 24.—Watson & Coulter, "Gray's Man. N. States," ed. 7, 93.

southward to Alabama and Arkansas. It was cultivated as long ago as the middle of the last century; but when found now in European gardens it appears to be grown under the name of *H. Kalmianum*. It has inhabited the Arnold Arboretum for several years, having been first received from Woolson & Co., of Passaic, New Jersey. It is perfectly hardy here, grows rapidly in ordinary garden soil, and flowers regularly and profusely every summer.

H. densiflorum † (Fig. 67) is a rarer and less known plant than *H. prolificum*, to which it is closely related. It attains a height varying from two to six feet, with stout stems divided above into many slender erect branches covered with leaves which are linear-lanceolate, with slightly revolute margins, and which are tipped with short stout mucros. The numerous flowers, which are rarely more than half an inch in diameter, are crowded in broad, compact cymes. The capsule is short and remarkably slender, and serves, as do the smaller flowers, to distinguish this species from *H. prolificum*, which it often resembles in certain New Jersey forms in the shape and breadth of the leaves, which are sometimes almost as broad as those of that species, and which have sometimes caused it to be considered a variety of it.

H. densiflorum is found from the Pine-barrens of New Jersey to Florida, Kentucky, Arkansas and Texas. It was received at the Arboretum last year from Kelsey Brothers, now of Linville, North Carolina, and flowered sparingly in August of the same year and profusely during the present season. It promises to be perfectly hardy and to become an interesting and beautiful garden-plant. C. S. S.

Some Recent Portraits.

THE October number of the *Botanical Magazine* contains a portrait of *Nepenthes Curtissii* (t. 7138), a tall-growing, stout, Bornean species of comparatively recent introduction. The pitchers, which are the only ornament in these plants, are described as eight to ten inches long by two wide, nearly cylindrical, but narrowed toward the base, yellow-green in color and mottled and marbled with red-brown. The fringe which surrounds the orifice is half an inch broad, brown, and faintly striated with a denticulate margin.

There is a good figure of *Vanda Amesiana* (t. 7139), already noticed more than once in this journal. The native country of this handsome plant, Cambodia, is now first made known. The delicious fragrance of the flowers, their chief charm, is hardly sufficiently emphasized; and the editor has overlooked the fact that the species was named in honor of an American Orchid-lover whose collection of these plants is not surpassed by any other.

There are figures of *Iris Danfordiae* (t. 7140), a pretty yellow-flowering species of the Cilician Taurus, and of *Clerodendron paniculatum* (t. 7141), a widely distributed shrub in eastern Asia, "and a great ornament whether in the jungle or in gardens"; and of a showy East India Orchid, *Saccolabium bellinum* (t. 7142).

In the *Gardeners' Chronicle* of October 4th there is a figure of *Lilium Henryii*, the new Chinese Lily, which resembles the Tiger Lily in the shape and size of the flowers. It has, however, broad leaves like those of the Japanese *L. auratum*, and does not produce bulblets in their axils like the Tiger Lily. The perianth-segments are less imbricated than those of that species, and are bright yellow, with a few minute reddish brown dots and a few large basal papillæ. This is one of the many interesting plants discovered by Dr. Henry in western China. *L. Henryii* flowered at Kew during the past summer, bulbs having been sent by the Superintendent of the Hong-Kong Botanic Garden.

The colored plate in *The Garden* (London) of October 4th is devoted to *Gardenia Stanleyana*, a beautiful plant from west tropical Africa rarely seen in gardens, although it was introduced early in the century through the efforts of the Earl of Derby, who sent a collector to explore upper Guinea botanically. It is difficult to understand why such a desirable plant should ever have been allowed to disappear from gardens, for certainly few stove plants produce more beautiful or more fragrant flowers. These are nine inches long, with a long

slender tube and five-parted limb fully three inches across when the flower is fully expanded. The exterior of the tube is deep, rich, vinous purple, while the upper or inner surface of the limb is pure white, covered more or less completely with oblong dots arranged closely in lines, the interior of the corolla-tube being of the same color as the exterior. The texture of the flowers is thick and fleshy, and they emit a powerful fragrance. Three other species of west African Gardenias have been cultivated at different times, and all are desirable stove plants. Being natives of one of the hottest and moistest regions of the world, they only thrive in the stove, where they require rich soil and abundant water and sunlight.

Judged by the beautifully colored plate published in the issue of the *Revue Horticole* which appeared on the 1st of October, an east Asia herbaceous vine, discovered by the Abbé David and described by Carrière as *Vitis rutilans*, must be an exceedingly attractive plant. Its principal beauty is due to the brilliant bright red subspinescent hairs which beset the stems and appear also on the buds, tendrils and on the principal veins of the young leaves, which are covered on the lower surface with rose colored pubescence. The mature leaves are deeply cordate at the base, scarcely lobed and provided with stout spinulose teeth; they are large and thick, lustrous on the upper and glaucous on the lower surface. The male flowers, which are the only ones described, the female plant not being in cultivation, are produced in large clusters and are bright red and nearly scentless. *Vitis rutilans* is one of the earliest of all the vines grown about Paris to begin its growth in the spring, and the young shoots are developed before any of the wine Grapes show any indication of starting into growth. According to Monsieur Carrière, "*Vitis rutilans*, to speak generally, has, as an ornamental plant, two distinct phases, one vernal, due to the brilliant coloring of its parts, the other to its large rich foliage, which it produces until the appearance of frost, and which makes it one of the most ornamental plants yet known, especially for covering arbors or ruins, or for hiding walls and other unsightly objects."

Foreign Correspondence.

London Letter.

AN exhibition of fruit grown in the British Isles was held on the first three days of this week in the Guildhall, London. The place was as novel as the exhibition was imposing; probably in no exhibition hall or tent in England or elsewhere has there been so extensive and meritorious a collection of apples and pears. There were 4,500 dishes of fruit, and they occupied 7,000 square feet of tabling. Notwithstanding the reported failure of fruit crops this year the exhibits were generally excellent. Dr. Hogg, the venerable master in fruit knowledge, declared that "in no fruiterer's shop in London, where the best obtainable specimens are procured from various parts of the world, could such apples be found as those represented in hundreds of dishes at this exhibition."

With a view to promote the general cultivation of hardy fruit the Company of Fruiterers of the City of London decided to offer prizes for collections of fruit to be exhibited at the Guildhall, and nearly a thousand pounds were set apart by the Company to cover expenses. No charge for admission was made; on the contrary, tickets of invitation were distributed freely. The result was that about 50,000 people visited the exhibition.

Exhibitors were classified in such a way as to make the competition as fair as possible. As growers in some portions of England are much less favored by nature than are others, the country was divided into three zones—namely, northern, south-western and south-eastern. There were also sections for cottagers and for small tenant farmers, while nurserymen were separated from amateurs and gardeners. Another special section consisted of growers within a radius of seven miles from the Mansion House.

Amongst the best of the apples exhibited were Gravenstein, represented by many dishes of large, well colored fruit; Ribston Pippin, good average fruit, much better than the unfavorable summer could have been expected to produce; Warner's King, Stirling Castle and Peasgood's Nonsuch. Of the last named there were many magnificent examples, and a dish of them shown by Mr. S. Barlow, of Manchester, famous as an Auricula-grower, was declared the finest dish of apples in the exhibition. There were five fruits in this dish, and they weighed nine pounds two ounces.

Pears were not of such uniform excellence as apples, although there were no really poor samples. The best of them included such proved sorts as Marie Louise, Beurré Superfin,

† *Hypericum densiflorum*, Pursh, "Fl. Am. Sept.," 376.—De Candolle, "Prodr.," i., 547.—Coulter, *Bot. Gazette*, xi., 84.—Watson & Coulter, "Gray's Man. N. States," ed. 7, 93.

H. galioides, Pursh, l. c., 376, not Lamarck.

Louise Bonne, Beurré Diel, Pitmaston Duchesse, Doyenné du Comice, Glou Morceau, Fondante d'Automne, etc.

With the Fruiterers' Company, the British Fruit Growers' Association and the Royal Horticultural Society earnestly at work as they are, the capabilities of England as a fruit-producing country ought to be fully tested.

MANURE FOR ORCHIDS.—I once asked a famous Orchid-grower his opinion of the wisdom of those growers who rec-

Glasnevin, has gone much further than this, and has used it for many epiphytal kinds with almost invariably good effect. In a paper which he prepared for the Scottish Horticultural Association, Mr. Moore relates his experience in testing Orchids with a chemical manure known as Fish Potash. This he used for various species of *Cypripedium*, *Dendrobium*, *Cœlogyne*, *Lycaste*, *Maxillaria* and *Sobralia*, all of which were so much benefited that he determined to make further experi-

Fig. 66.—*Hypericum prolificum*.—See page 524.

ommended the use of strong soils and manures for various Orchids. His reply was: "They may or may not be right; but of one thing I am certain, every Orchid without exception may be grown in peat or sphagnum, or the two combined." Professor Reichenbach was opposed to the use of manure in any form for Orchids, and I will remember his warning when he saw cow-manure water being used in our Orchid-houses for damping down in the evening. But it was long ago proved that for such Orchids as *Pleiones*, *Phajus*, *Calanthes* and similar terrestrial Orchids, manure is beneficial. Mr. Moore, of

ments—fish-potash guano becoming "a regular article on the Orchid-bench at Glasnevin." He found that *Anguloa Clowestii* and *Houlletia Brocklehurstiana* showed most marked improvement in growth when fed with this manure. The *Houlletia*, he says, "has always been more or less a puzzle to Orchid-growers. Some grow it cool, some warm, and but few really succeed with it—that is to say, succeed in growing and keeping for any considerable period nice, healthy, flowering specimens, and I confess I had not been one of these; in fact, I despaired of getting it to grow in a satisfactory manner. But

a change came over it as soon as I commenced to manure it, and I have no difficulty in growing and flowering *Houlletias* now." All *Cypripediums* made better growth when fed with this manure than when grown in ordinary soil. After three years' careful experiments Mr. Moore concluded that "the continuous use of fish manure is beneficial to Orchids; the benefit is not equally apparent each year; and lastly, the beneficial effects are most marked during the second and third

it. These remained healthy, but they did not grow as freely—that is, the new growths were not so large as the older growths, and the number of breaks were not so numerous; in fact, they evidently missed the manure." The growth made under the influence of manure was sound and healthy, and the production of flowers excellent. Mr. Moore recommends the following precautions in using this manure for Orchids—namely: Give it in small quantities, and only once a year; mix it well

Fig. 67.—*Hypericum densiflorum*.—See page 524.

years. At the third year the plant seemed to attain the maximum size of leaf and pseudo-bulb, and during the fourth and fifth years all I could do was to maintain the standard of excellence arrived at during the third year, but there was little difficulty in doing this when a little manure was used and ordinary precautions observed. I made certain that the annual addition of manure was necessary by withholding it from about half a dozen plants which had been previously supplied with

with the soil, or, in the case of plants not to be repotted, raise the sphagnum and scatter the guano over the soil.

I have referred to this subject and quoted Mr. Moore at some length, because I know him to be a first-rate Orchid-grower and a keen and accurate observer. The collection of Orchids, mainly formed by him within the last twelve years, is one of the most comprehensive and best managed in the British Islands.

HARDY AUTUMN FLOWERS.—Amongst the best of these in bloom now—in the second week of October—are the following: Belladonna 'Lily—a border filled with this plant, under the lee of a warm-house wall facing south, is covered with the tall spikes of flowers of this beautiful Cape bulb. The color varies from white, tinged with rose, to a rich rose-red; the trumpets are numerous and durable as well as beautiful; one does not hesitate to declare that this plant has no equal among hardy autumn-flowering bulbs. The Belladonna Lily requires a warm wall and it must not be disturbed when once planted, unless the bulbs become crowded.

In the same border with the Belladonnas is a large group of the rich colored Cape Irid, *Schizostylis coccinea*, with lily-shaped flowers. From the middle of September until the middle of November they will be beautiful, unless there is a very sharp frost; they are not affected by a degree or two, merely close their cups until the sun comes to warm them into expanding again. An edging of the autumn Daffodil, *Sternbergia lutea*, one of the brightest of yellow flowers, is beautiful in itself, and harmonizes with the rich crimson of the *Schizostylis*. A bed of the new *Anomatheca grandiflora* is an attraction of more than ordinary interest. Evidently, this plant will prove as useful for autumn effect as the *Schizostylis*, for its large rich crimson and maroon flowers come at the same time and are almost as effective.

Tuberous Begonias.

IN the absence of frost hybrid tuberous Begonias still make a brave show out-of-doors, though they have about ceased to grow and few new flowers are expanding. The exact value of these plants for bedding in this latitude is yet to be determined. Last summer with much wet weather and inclination to coolness beds of Begonias were very attractive and successful with little care. This season they do not appear to have done so well unless carefully watched and tended. My plants, at least, seemed to halt in their growth, were not nearly so floriferous and were attacked by black rust. The claim often made that tuberous Begonias are the coming bedding plants is hardly likely to prove true. In the first place they require, from the nature of their growth, more care than most people, not professional, are willing to give bedding plants, and they need selected situations with a certain amount of natural shading. Even when carefully hardened they are often burned by a fierce summer sun, and in some conditions of climate are quickly attacked by rust. But with a careful selection of varieties of dwarf growth and stiff peduncles, beautiful bedding effects may be made with these plants, and they are well worth the necessary care.

Probably no flowers suffer less from continued drenchings and no blooms are more showy. An unpleasing color is seldom or never seen among them. The improvement of the hybrid Begonias has not yet ceased. Growers are now giving their attention to strains of dwarf growth, and, with rigid peduncles, carrying flowers well above the foliage. As greenhouse flowers tuberous Begonias leave little to be desired, brightening up the house from early July to late in the year; in fact, some of the Socotrana hybrids carry the season through the winter. In the greenhouse they require all possible air and judicious shading. Hitherto we have had no fragrant tuberous Begonias, but a species has been collected in South America whose flowers have a distinct and agreeable fragrance. This Begonia, known as *B. Baumanni*, will probably enable hybridizers to give us a race of hybrids in which perfume will give a perfect charm to the admirable blooms.

Besides the hybrids with great showy blooms, some of the smaller blooming species are now specially attractive. *B. geranioides*, from a low cluster of round leaves, throws up numerous racemes of dainty flowers, whose pure white is accented by a dot of golden stamens. The plant has a curious resemblance to a Pelargonium, and is from Natal, as is also *B. Natalensis*, which has been before noted in these columns as a very pleasing and distinct variety with small dark orange flowers and metallic green foliage. *B. Martiana grandiflora*, *racemiflora* and *diversifolia* are three varieties of *B. gracilis* which can be recommended to all lovers of dainty beauty in plants. From the tubers are thrown numerous gradually lengthening stems, on which expand a succession of pink flowers, producing an effect as unique as it is pleasing. *B. Martiana* is an old introduction from our south-west border or northern Mexico, I believe, but is even yet apparently not well distributed.

The Newer Gladioli.

LAST year much was said in the papers about a strain of Gladioli which had been produced in California, but I am sorry to say that these sorts, of which I had formed such high expectations, are not what we consider very good flowers in the vicinity of Boston. None of them withstand the sun better than our ordinary kinds; none of them have flowers above the ordinary size; none of the flowers have colors or shadings which would cause particular notice. Shasta is the best one, and is of that type of which there are so many—white, marked with rose.

The new strain raised by Lemoine, of Nancy, France, is a noble addition to our resources. He calls them the Nanceianus strain, and says they are raised from the ordinary Gandavensis sorts, fertilized with *G. Saundersi*, and their appearance confirms it, for they have much of the peculiar shape and marking of that species. I tried the same cross some years ago and got insignificant and inferior flowers, which shows that some hybridizers are more expert than others. These flowers are very large, surpassing, in fact, the promised size of the California strain. The largest is President Carnot, some of whose flowers I found to have a breadth of six inches. None of them can be said to be very good in color, but not only that, but the size of spike will be greatly improved now that the break has once been made.

I wish also to advocate the claims of some of the hardy Gladioli. Last fall I planted several hundred of these, which I covered with leaves and corn-stalks. As far as I could judge every one came up and bloomed to my complete satisfaction, beginning about June 15th and continuing to come forward in the several sorts up to the end of July. The earliest was *G. Segetum*, a species attaining a height of two feet, and producing rosy purple flowers of good size, adorned with white central stripes on the lower petals. Next came *G. communis*, with colors like the last, but with flowers of different shape and of longer duration. Then *G. Colvillei*, and *G. Colvillei albus*, or Bride, the first purple and straw, the other a beautiful white, opening with a creamy tint in the centre, which soon bleaches as white as snow. Many varieties of *G. ramosus* (a hybrid, as is also *G. Colvillei*) were conspicuous, their colors being the most vivid scarlet, crimson and rose, generally with white markings. My favorites, however, among the hardy kinds are what are called Nanus varieties, which have been produced by Dutch bulb growers by crossing many dwarf species. These only attain a height of ten or twelve inches, but their flowers are most delicate and exquisitely soft and tender in tint. They deserve to be largely grown for bouquets, for which their size and lovely colors so well adapt them.—W. E. Endicott, in *Popular Gardening*.

Cypripedium Morgania.

AS far as raising artificial hybrids among Lady-slipper Orchids is concerned, the culminating point of the hybridist's art may for the present be looked upon as embodied in *Cypripedium Morgania*. This magnificent addition to the floral world appeared ten years ago in Messrs. Veitch's nursery, Chelsea, through the agency of their foreman, Mr. Seden, who in his time has contributed many other beautiful hybrids to our Orchid-houses. The plant was raised by fertilizing the stigma of *C. superbians* (otherwise known as *C. Veitchianum*) with the pollen of the distinct and robust-growing *C. Stonei*, and was named in compliment to the late Mrs. Morgan, of New York, who took much interest in the great Orchid family. The parents of *C. Morgania* are by no means of a delicate constitution, but their offspring may be said to be as vigorous as both of them put together, if I may be pardoned for using a phrase tainted with Hibernian proclivities. Indeed, *C. Morgania* may be considered as one of the very strongest growing Cypripediums in cultivation, and this fact, in connection with its large and handsome flowers—which (with the exception of *C. Stonei platytanum* perhaps) are the largest in the genus—has led to its extensive propagation, so that one frequently sees it. Perhaps the finest specimen of Mrs. Morgan's Cypripedium is at present in the equally fine collection of Baron Schröder, near Staines. At a meeting of the Royal Horticultural Society in August last spikes were exhibited from this plant bearing as many as four and five large flowers, a number hitherto unsurpassed in its history as far as I am aware. The broad, strap-shaped leaves are a foot or more long, bright green, with darker green transverse narrow bars. The large upper sepal is creamy white, flushed with delicate rose at the sides, and longitudinally traversed by seven or eight broad, deep purple lines. The lower sepal is somewhat

smaller and with fewer purple lines. The broad, drooping petals are between four and five inches long and are fringed with grizzly blackish hairs on the margins, while the surface, which is olive-green just at the base, passing into pale yellowish white, is densely covered with large irregularly shaped blotches, these being purplish pink on the anterior portion and dark purple at the base, the difference in their color being due no doubt to the variation in the ground color. The pouch is very large and pointed, and may be described as purplish pink at the end and gradually softening into rosy brown under the edge of the mouth. The inflexed basal lobes are creamy white, spotted with purple, and the large shield-like staminode is buff-yellow and pubescent.

Last year a variety known as *Superbum* appeared in the collection of Sir Trevor Lawrence, having been raised from the best varieties of *C. superbiens* and *C. Stonei* obtainable at the time of crossing. This variety is characterized by having more highly colored flowers, and slightly shorter, broader and more heavily blotched petals than the ordinary variety. It is finely figured in the last issue of *Reichenbachia*.

As mentioned before, *C. Morganæ* is a very vigorous grower, and consequently may be easily cultivated. It likes a tolerably warm and moist house, and may be potted in a compost of fibrous peat and loam in about equal proportions. Water may be freely given during growth, and more or less frequently at other times, except in very dull and cold weather, when little will suffice.

Isleworth, London.

John Weathers.

A Few Flowering Plants.

Rogiera gratissima is a useful ornament for the intermediate house, or warm greenhouse, and deserves to be more widely known and grown; for though this plant has been in cultivation for many years it has not yet become common. It might be described in a general way as being the cool-house representative of the *Ixora* type of decorative plants, the *Rogieras* also belonging to the *Rubiaceæ*, as do the *Ixoras*, though the former are found at much greater elevations than the latter.

Rogiera gratissima is a hard-wooded shrub with simple, opposite leaves of bright green, and terminal clusters of pink flowers which have some resemblance to those of a *Bouvardia*. The flowers are fragrant and last fairly well when cut, and as they are freely produced at intervals during both summer and winter, the value of this plant will readily be seen. *Rogiera gratissima* is propagated by means of cuttings, which should be made of firm growth; for instance, from short side shoots that are about half ripened. The cuttings require a rather close atmosphere until they become calloused, after which they soon produce roots, and may be potted into a light mixture consisting of two-thirds good loam to one-third peat, to which should be added a liberal supply of sand. As the plants become larger a similar mixture should be used for potting them in, but the compost should be coarse and well drained.

Another fine flowering plant is *Dalechampia Roezliana rosea*; it is seldom seen, though easily managed and decidedly ornamental. This *Dalechampia* is very useful in small plants, as its striking inflorescence shows to good advantage. It is a native of the West Indies and enjoys a warm and moist atmosphere; under such conditions its growth is rapid, the most satisfactory plants being those grown from seeds, which germinate quickly when placed in a warm house. The chief beauty of this plant is found in the bracts surrounding the flowers, these being quite large and deep pink in color, while the flowers are yellow and rather insignificant. The leaves are from five to six inches in length and have a peculiar drooping habit.

Dalechampia Roezliana rosea seeds freely, but the seeds should be gathered as soon as they are ripe, for mice have a special liking for them. As regards soil, the *Dalechampsias* are not specially fastidious, almost any light, rich compost being suitable, provided there are the necessary conditions of warmth, moisture and moderate shading; at the same time proper attention should be given to the drainage of the pots, as these plants will not grow well in sodden soil.

Posoqueria longiflora is a fine hard-wooded stove plant from Guiana, and well deserves its specific name, for the tubular white flowers are much elongated, and may be described as having the appearance of a large *Stephanotis* flower with an abnormally long tube. The leaves are somewhat ovate in shape and dark green in color; the plant grows in bush form, and ultimately becomes a small tree. It makes more progress in a warm-house, but may be grown in a temperature of fifty-five degrees, providing it is not over-watered. *Posoqueria longiflora* is propagated by cuttings, which should be of firm

young growth, and placed in a rather close atmosphere until rooted; and as this process is somewhat slow, some little care is required to prevent them from damping off. When rooted they should be potted in a compost similar to that recommended above for *Rogieras*, in which they will thrive if given reasonable care.

A pretty little member of the *Lobeliaceæ* is found in *Siphocampylos Humboldtianus*, a plant of South American origin, also known as *S. fulgens*. This plant bears bright scarlet tubular flowers about two inches in length, and has dark green leaves of small size, smooth on the upper surface, but more or less pubescent beneath. *S. Humboldtianus* is of shrubby habit, and needs to be pinched in occasionally to keep it in good shape. It is propagated also by means of cuttings, which may be rooted almost as readily as those of a *Verbena*, though not in so short a time. No special directions regarding soil for this plant are needed, as good loam is all it requires; and given a temperature of fifty-five degrees, with a little protection from full sunlight, a measure of success is assured.

W. H. Taplin.

Notes on Shrubs.

IN view of the fact that it is likely soon to be quite extensively advertised, it may be well to note that the plant which has formerly been referred to in these pages as *Symphlocos paniculatus* should properly be called *Symphlocos cratagoides*; the latter is the name accepted by botanists generally and the one most commonly used. One firm of plant-dealers already have *S. cratagoides* on their lists, and it is desirable that there should be uniformity with regard to names of plants in the catalogues of nurserymen. In this instance, for example, it would be very misleading and confusing to amateurs to find a plant described in one catalogue as *Symphlocos cratagoides* and in another as *S. paniculatus*, each probably with descriptions so various as to give an impression that they are different species, when they are in reality identical. All honest dealers will work toward a uniformity of names, and those who employ little used or disqualified names are usually more or less unreliable and are best avoided.

S. cratagoides occupies a unique place in the shrubbery on account of its bright ultramarine blue fruit, which ripens in September, and its innumerable small white flowers, which are produced in the last days of May or early in June, and have a very light and pleasing appearance, although much hidden by the foliage of the growing shoots. The rough, thick leaves have no very peculiar qualities of an ornamental character; they are usually clean and free from disfigurement by disease. This plant may attain the size of a large shrub or small tree, and is of rather loose and irregular habit of growth; indeed, as its specific name indicates, the general appearance of the plant in some respects is much like some of our smaller species of *Cratægus* or Hawthorn, although the flowers and fruit differ widely. The thin fleshy portion surrounding the seed of the fruit is rather dry and unpleasant to the taste, while the seed is strongly pungent or almost acid; but birds, especially robins, seem very fond of it. *S. cratagoides* shows considerable variability in cultivation in regard to vigor of habit, quality of foliage and coloring and maturing of fruit.

This tendency to vary is also shown in herbarium specimens from different places where the plant has been found, and it appears to have a wide distribution in northern India, in China and in Japan. Victor Jacquemont, in his celebrated Oriental travels, found the plant at an elevation of from 7,500 to 8,000 feet, and in his "Voyage dans l'Inde" (atlas, tab. 110) is given the only figure which appears to have been published. It is drawn by the eminent artist Riocreux, and represents a flowering branch and analyses of the flowers, the mature fruit being at that time apparently unknown. The description (vol. iv., p. 103) was furnished by Decaisne, who called it *Lodhra cratagoides*. The name "Lodhra" is said to have been derived from the Indian word "lodh" applied to this and another species (*S. racemosa*) from which a yellow dye is procured. Lodhra was first used by D. Don to designate a section of the genus; later it was given a generic place by Decaisne; Bentham and Hooker include it under the old generic name of *Symphlocos*.

In striking contrast to the bright blue fruit of this *Symphlocos* we have the snow-white berries of *Symphoricarpos vulgaris* and the bright scarlet color of the native Hollies or Winterberries. Of the latter, the Smooth Winterberry (*Ilex laevigata*) is the earliest to ripen fruit, and it begins to turn red about the same time that the first fruit of the *Symphlocos* changes from green to greenish white and then blue.

It has been stated in botanical descriptions that the berries of *I. laevigata* are larger and less bright than those of the

common Winterberry or Black Alder (*I. verticillata*). This certainly does not appear to be the case in cultivation; the fruit of *I. laevigata* is little if any larger, and although it is less abundant, its color is quite as bright and rich a scarlet as that of the other species, and it ripens from two to three weeks earlier. The foliage is smooth and glossy, giving the whole plant, when in full fruitage, a very showy and attractive appearance. The leaves of *I. verticillata* are rougher and more deeply serrated and are not so glossy. The fruit is more abundant, and probably the dense, short, axillary clusters, which almost encircle the branches, gave rise to the rather misleading name of "verticillate," or whorled.

Although these two species have strong resemblances, they each have distinct and constant characters by which they may be readily identified. Both form erect, compact bushes under cultivation. For general purposes in ornamental planting, *I. verticillata* is probably the most valuable, as its more abundant fruit remains in good condition for the longest time in the autumn and winter.

Arnold Arboretum.

J. G. F.

Kniphofias from Seed.—The smaller growing kinds of Kniphofia, such as *K. Macoweni*, produce seed freely and ripen it much better than those that flower later. *K. corallina*, *K. nobilis* and *K. Saundersii* are, I believe, all of garden origin, and, when obtained true, are among the best of the older and tried varieties. One European grower is said to have as many as sixty kinds in his grounds. I would advise those who have raised these plants from seed not to place much reliance on their being true to name, as these Torch Lilies, so conspicuous in the garden, are equally so to bees and other insects. Where more than one kind is grown it is impossible to get any variety true from seed, though there is the possibility that one may raise plants of more value than the parents, as I have done on more than one occasion. I have not seen a better kind than *K. corallina*; it is the most constant bloomer of all, commencing soon after midsummer, and it continues until frost. The spike is very dense and compact; in habit it is intermediate between *K. aloides* and *K. Macoweni*. These plants are indispensable in a well arranged flower border. In the eastern states none are hardy, though some may live out-of-doors through a mild winter, but it will take a season for them to recover and to flower again. It is a simple and safe plan to lift the roots and cut off the tops to within twelve inches and winter in sand in a cool cellar. They should be taken out early in spring, before they begin to grow, and planted in rich soil. These plants will repay liberal treatment.

South Lancaster, Mass.

O.

Lælia Eyerermaniana.—During the months of July, August and September plants of this attractive Lælia may be met with in various collections showing their flowers. At present it is little known, owing chiefly to the fact that there are not a great many plants in cultivation, and also because it has only been introduced about two years, having been imported in 1888 by Messrs. Sander & Co., of St. Albans, with a consignment of *Lælia majalis*. It is generally supposed to be a natural hybrid between this latter species and *L. autumnalis*, and there is every reason to believe that such is the case, inasmuch as it is impossible to distinguish the pseudo-bulbs of *L. Eyerermaniana* from those of *L. majalis*, while the flower is intermediate between the two species as far as structure and markings go, but, curiously enough, is much smaller than either *L. majalis* or *L. autumnalis*, a fact which seems difficult to explain. Last year I saw about a dozen plants in flower at one time, and there was little or no variation to be noticed in them, except in the number of blooms borne on the peduncles, some of which bore as many as ten and twelve flowers, while others had as few as three and four. The ovate-acute sepals and rhomboid-acute petals are of a clear rose-purple, the sepals being remarkable for having a greenish knob at the tips. The erect lateral lobes of the lip are white, with divergent lines of violet or purple spots on the inner surface, while the broad, obovate-apiculate front lobe is dark rose, with deeper colored veins on each side. On the disc are two elevated, violet-spotted keels, which become constricted about midway, then open out again, when a third yellow keel appears between them. The slightly curved column is pure white, except at the base, which is pale yellowish green, spotted with violet. The pseudo-bulbs are ovoid, more or less wrinkled according to age, and have two or three deep green, oblong, leathery leaves, about six inches long on the summit, both leaves and bulbs, as before mentioned, resembling those of *L. majalis*.

As years go on, and *L. Eyerermaniana* becomes more plentiful, one may expect to meet with it more frequently than at present, especially as it produces its flowers freely and re-

tains them in a fresh condition for several weeks. The plants are best suited for basket culture, and may be suspended near the roof, so as to obtain plenty of light. They will thrive in a cool house, although it is beneficial if a slight increase in the temperature be made when they first begin to push their young growths, the strength of which must act as a guide for the amount of water to be given. A cool, dry atmosphere will be found to keep the flowers in greater perfection than a warm, moist one, which soon causes the flowers to be spotted.

The specific name is given in compliment to Mr. J. Eyeraman, of Easton, Pennsylvania, who, I believe, has a splendid collection of Orchids.

Isleworth, London.

John Weathers.

Amaryllis Belladonna.—The beautiful Belladonna Lily, as it is popularly called, flowered with me this autumn for the first time. Early in the spring I purchased a few strong bulbs, which I planted in the latter part of May in rather poor sandy soil near the wall on the south side of my house, where they have all the sun-heat necessary for their development. Early in September the largest bulb pushed up a flower-stem which reached a height of about twenty-two inches. It was dark reddish brown in color, overlaid with a delicate light bloom, like that on some grapes. The flower-buds were rosy red, and the flowers at the time of opening light rose with a yellowish white throat, changing to dark rosy shades on the second day. There were eleven flowers in the umbel, and each one lasted in full beauty more than a week. This umbel of well opened flowers, glittering in sunshine as if sprinkled with ice, was a beautiful sight to look at. The perfume of the flowers was sweet and spicy. In the northern and eastern states the Belladonna Lily must be grown in pots, as it will not endure in the open air the rigors of our winter climate. It would be interesting to know if this plant succeeds in the open air anywhere in the south. I tried to grow it in Florida, where the soil is sandy, but without any marked success. Apparently, the heavy rains there in summer, when all these plants are resting, are fatal to their health.

The home of *Amaryllis Belladonna* and its varieties is in the south-western part of the Cape of Good Hope, where it grows in great abundance. *A. blanda*, which is described in the excellent "Hand-book of Amaryllideæ," by Mr. J. G. Baker, as a variety of *A. Belladonna*, appears to me to be a good species, the bulbs being larger, dark brown and egg-shaped, while those of *A. Belladonna* are brownish gray and nearly globular. The flowers of *A. Belladonna* are more open, rosy white and more fragrant. The so-called *A. Hallii*, which I have always supposed to be near *A. Belladonna*, is now referred by Mr. Sereno Watson (GARDEN AND FOREST, vol. iii., p. 176, Fig. 32) to a distinct genus, *Lycoris*. In addition to this species, *Lycoris squamigera*, I have in cultivation *L. radiata*, *L. radiata Terraciniiana* and *L. aurea*; none of these, however, have flowered yet.

Milwaukee, Wis.

H. Nehrling.

Correspondence.

Kansas Farmers and Kansas Forests.

To the Editor of GARDEN AND FOREST:

Sir.—Though Kansas possesses no timbered area that, for extent or density, will compare with the forests of the eastern or middle states, there is a considerable extent of country along the eastern border which was originally well clothed with trees—in the bottoms a heavy and valuable growth, on bluffs and uplands a scattering stand of scrubby Oaks and Hickories. Farther west the timbered area is narrowed and confined more closely to the streams, and beyond the junction of the Blue with the Kansas River the last wooded hills are seen. Beyond this point the trees on the slopes of the bluffs disappear, and only the banks of the streams and the lower benches are wooded. Before the head waters of either of our larger western rivers are reached, the last solitary Cottonwood or Elm will have been passed and the Buffalo Grass and the Blue-stem are masters of the field.

The trees are not keeping their bounds without attempting to acquire territory, and every rod of soil where the fires cannot sweep is sooner or later covered with timber. A bend of a stream nearly surrounding a bit of bottom land affords the best chance for an advance if the fires are prevented from entering from the unprotected side. Where natural conditions or the care of man afford this protection we soon find those advance guards of forest-growth, the Sumach and the Dogwood-bushes, springing up among the Blue-stem Grass. Before long from the midst of these thickets young Oaks, Walnuts and Elms shoot up, and in a score of years form a handsome

grove. Out along some narrow ravine or draw leading down from the bluffs the trees push their way, year after year, where fires have failed to reach them. Then comes a wet season, with an unusual growth of Grass, a dry day, with the wind in just the right direction, and the fire sweeps down, deadening the young growth back nearly to former limits. But the sturdy roots are left alive, and the contest is renewed till, at length, the trees overshadow and drive out the Grass, and so deprive the fire of fuel.

With the general settlement of the country came the steam saw-mill and the demand for all grades of native lumber, as well as for thousands of loads of stove-wood. Many of the owners of timbered lands, reckless of the future, sold their trees till not a valuable stick was left. The trees that stood upon the land of a non-resident or upon state or school lands were chopped and plundered by day and by night. Cases could be cited in some of the western counties where a fine growth of Red Cedars was so completely cleared from the bluffs that neither stumps nor roots now remain in the chalky declivities to give a hint of the verdure that once covered them. Kansas pioneers dealt with the scanty growth of timber they found with the same reckless disregard for the future which led to the extermination of the White Pine farther east. Those who settled first and secured timbered claims had more than enough wood for their needs; the prairie homesteader had none. It is perhaps not just or consistent to blame too severely these early pioneers who came to the state often with little besides the team and wagon which brought them. With the nearest railroad station fifty or a hundred miles away, where Pine-lumber of poor quality could be had only at enormous prices, it was natural that as much as possible of the native timber should be turned to account. But there is a waste and destruction of young timber taking place to-day against which the warning voice cannot be too earnestly raised. It may sound strange to speak of clearing timber land in Kansas, yet it is a fact that within a single county, during the past few years, many acres of thrifty young timber have been chopped and placed on the market as stove-wood or fence-posts. I have seen scores of young Black Walnut-trees, not thirty years old, split into rails and fence-posts, without a thought on the part of the owner that the supply of merchantable Walnut-lumber in the east and south is nearly exhausted, and that he was clearing the ground of trees which would be of great value to his children. A slaughter like this is often made to secure one more field for Corn or Wheat, and this by a man who has already more acres under the plow than he can bring to one-half of their productive capacity.

In spite of much chopping and a great deal of abuse, the timbered area of Kansas is probably greater than it was thirty years ago, though the number of trees that would afford profitable saw-logs is comparatively small. Where a wise foresight has been exercised we find valuable varieties which will soon do to draw upon for lumber. Oak and Walnut spring up readily where older trees of those sorts are established to furnish the seed. The Green Ash soon gains a footing on moist land and makes a rapid growth while young. Several species of Hickory spring quickly into valuable groves in the more eastern portion of the state. In fact, wherever trees have obtained a hold there is abundant encouragement for the man who will protect them and give them a chance.

When the farmers who own the timbered lands make it a rule to cut only mature trees or crowded and imperfect ones, except when needed for special use, thinning judiciously and preserving with care every young tree of a valuable variety; when timber-lands are as carefully guarded from fires as the stock-yards and stables, and when cattle are not allowed to tramp out the young seedlings for the sake of the scanty pasturage furnished by the woodland, the value and profit of Kansas forests will steadily increase.

We need not expect to see Kansas lumber quoted in the great markets of the nation, but we may see many domestic wants supplied by it in the way of fuel, fencing, and of the ever needful material for buildings and implements upon the farm, at a time when the hardwood forests of the southern states are no longer sold at the Government price per acre, and when the manufacturer's supplies of hardwood lumber will be more difficult to obtain than they are at present. The commercial value of this young timber is not its only importance. The benefits to be derived from a dense growth of trees and underbrush on the low bench-lands of our rapid streams, in checking the force and destructiveness of floods, is beyond computation. When the uplands were covered only with Buffalo Grass, which was burned off every year, and the draws and water-courses were destitute of a tree or shrub to check the force of the current when it left the channel,

the suddenness with which an unimportant branch assumed the proportions of a navigable river can only be appreciated by a man who has been on the wrong side of one of them at nightfall, or who has, perhaps, seen his team washed down the boiling current while he was glad to cling to a friendly Elm-top and wait for the flood to run down. The replacing of Buffalo Grass by coarser and ranker varieties, the more ready absorption of moisture by cultivated fields, and the holding in check of the swollen torrent by the increased growth of trees and shrubs along the banks, have all tended to reduce the suddenness and destructiveness of the floods with which the early settler was so familiar. As a further indication of change for the better there are now many streams which flow nine months in the year where there were formerly dry channels except after heavy rains.

The future of Kansas forests must rest with Kansas farmers. Give the trees protection from fire and stock, with a little timely thinning and pruning; cut them as they reach maturity, and provide the way for others to take their places, and the woodlands will grow continually more valuable and yield a return as safe and sure as the best plowed fields.

Agricultural College, Manhattan, Kan.

Recent Publications.

The Art and Practice of Landscape-Gardening, by Henry Ernest Milner, F.L.S., Assoc. M. Inst. C. E. With Plans and Illustrations. London, 1890. Quarto.

The author of this book is an English landscape-gardener of experience, having begun his work as colleague of his father, Edward Milner, who was associated with Sir Joseph Paxton during his later years in all the works he then carried out. That Mr. Henry Milner's own tasks have been varied and important is shown by the references and illustrations in this book, which speak of large private places conceived and carried out by him on the continent as well as in England, and also of public gardens and cemeteries. The book is well written and handsomely printed; the plans are large in scale and printed in colors; and if the etched views had been as good in their way nothing but praise could be given to the externals of the volume. The text deals partly with general principles of taste as concerned with the different problems of the art and partly with the practical treatment of such problems.

The purely æsthetic chapters will, perhaps, do nothing to modify or enlarge the opinions or tastes of those already familiar with standard works on landscape-gardening, but they will give sound guidance to a beginner, and here and there we come across a passage where a familiar truth is particularly well expressed. For example, every one knows the generic difference between the formal gardening of Renaissance times and the "natural" or landscape method of treatment which developed in the eighteenth century. But this difference is freshly impressed upon the reader when he is shown that, while the later aim has been to simulate in a measure the aspect of untutored Nature—to bring, as has elsewhere been said, the country into the garden—the older ideal was to lay out the garden "for utility or for pleasure, with a purpose of distinguishing it from the surrounding scenery." Regularity and order then "contrasted with Nature's aspect outside," while to-day a carefully calculated irregularity and variety are made to harmonize with this aspect. Of course, the author's preference is in general for the modern naturalistic style, but it is agreeable to find how clearly he recognizes the claims of architectonic designing in certain places and cases. As in every other art, the mode of the day is apt, in gardening, to impose itself so strongly on the artist's mind and taste that he can see no good in any other mode, and instead of an enlightened adherent of the style he prefers, he becomes its unreasoning, and, therefore, often mistaken advocate. Thus, in this country as in England (and even on the continent, where one might anticipate a clearer recognition of the perennial claims of architectonic designing), we see constant errors in the treatment of small surfaces of ground and the arrangement of the areas close to dignified buildings. Tiny rectangular yards are laid out with a futile, trivial effort to obtain a "landscape effect," and palatial homes and public structures are made to look as though they had been casually dropped down on a bit of untouched ground, among trees, shrubs and grassy spaces where the presence of architectural factors had not been anticipated. From errors of this sort Mr. Milner's words should free the mind of any neophyte in the practice of his art. He perpetually insists upon the elemental fact that a large house should be supported, and its dignity and the beauty of its lines increased, by the arrangement of the levels and the planting

close about it—that, in short, something in the way of formal designing should make the transition between its formal lines and the graceful variety of the grounds further away. To make this transition well—to make the formal designing harmonize with the house on the one hand and with the true landscape passages on the other—is, of course, the most difficult of the artist's tasks; nor is it an easier task when buildings are not in question, but when, as in the case of a public park, certain elements of formality are still demanded for grandeur of effect or for convenience of public use. In learning how to treat such tasks much help, we think, will be afforded by the more practical portions of our author's text and by his plans. Especially interesting is his description of the transformation of an estate in Hungary, where he deflected a public road which passed too near the front of the old house, and arranged the ground on that side, as well as on the other sides, in what seems to be a very ingenious, intelligent and successful way. A special chapter of interest is given to "Terraces," and among the practical chapters, hot-houses, the kitchen garden and the economic treatment of land are dwelt upon, as well as those questions of arrangement and formation, of planting and of the treatment of water and of approaches, which one would be more sure to expect. Of course, certain counsels—as, for example, with regard to the most desirable trees and shrubs, lists of which are given for different soils and situations—will be of little use to the American as compared with the English student. But there is still much in the book to instruct the former, and we would especially call attention to the chapter headed "Water" as dealing with a subject usually less well understood than others. "The Approach" is another good chapter, illustrated with interesting plans. It is a question, however, whether, in the two large schemes for planting which are illustrated, the author's desire to secure variety has not led him to use too many species of trees. There is no scale appended to show the size of the intended boundary plantation, for example; but it would need to be very large, indeed, to admit, with good effect, of the introduction of the forty-four species whose names and places are marked thereon. Nor can there be many situations in which, for practical cultural reasons, it would be wise to mingle so large a variety of indigenous and foreign trees. On the whole, however, while the volume is in no sense a remarkable or very inspiring one, it can be recommended to the attention of serious students, especially those who are not able to read the many similar treatises which exist in the French and German languages.

Notes.

The forest-fires which have raged during the past summer in the Black Hill-region of Dakota are reported to be the most destructive which have visited that part of the country since it has been open to settlement. Sixty square miles of timber are said to have been burned over.

Discoveries made not long ago near the Stabiana Gate, in Pompeii, included the trunk of a tree which an Italian savant has identified as *Laurus nobilis*. Some of its fruits were likewise found, and from their size it is now said that the eruption which destroyed the city must have taken place in November, and not, as previously believed, in August.

According to the *Victoria Colonist*, one of the largest Douglas Firs ever cut in that vicinity was recently measured at a mill in Vancouver. It included four twenty-four-foot logs, the largest of which measured seventy-six inches in diameter, and all of which were perfectly free from knots. The whole product was estimated at 28,614 feet.

The true Apples do not, as a rule, assume any decided autumn coloring of foliage. The exception is the Japanese *Pyrus Torino*, a small hardy tree distinguished by its curiously lobed leaves, which resemble those of some species of *Cratægus*. These are now colored deep purple, and are very ornamental, and quite distinct from those of any other Apple-tree.

Mrs. Elizabeth G. Britton announces in the *Bulletin of the Torrey Botanical Club* that as there is a demand in the eastern states for a hand-book of Mosses smaller and cheaper than Lesquereux and James' Manual, and as, moreover, the edition of this is nearly exhausted, she is preparing an illustrated work to be called "A Hand-book of the Mosses of North-eastern America." The area denoted by the title will include eastern British America and the north-eastern and central states, and it is hoped that the volume will be ready for publication by the end of next year.

The autumn coloring of the foliage of the Japanese Negundo (*Negundo cissifolium*) is surpassed in beauty by that of few exotic

trees. The general color of most of the leaves at this time is bright orange. Those at the end of the branches turn first and are brilliant scarlet, the contrast between the two colors producing a beautiful and striking effect. *N. cissifolium* is a small, perfectly hardy tree of excellent habit and pleasing color through the summer. It is vigorous, grows rapidly, and so far shows none of the constitutional weaknesses which have made many other Japanese plants of the Maple tribe so unsatisfactory and disappointing in this country.

A writer in *Gartenflora*, speaking of the profusion of roof and terrace gardens which enliven the streets of Paris, mentions as one of the most remarkable the terrace-garden of Monsieur Lockroy, the father of Victor Hugo's son-in-law. Once a popular writer of comedies and operettas, Monsieur Lockroy is now above all an amateur gardener, and his "hanging garden," which lies twenty metres above the street, shows the results of thirty years' affectionate labor. Its care is entirely in his own hands, and in a multitude of pots he grows not only beautiful Roses and other flowers in profusion, but fine pears and peaches, apples and luscious grapes, which clothe a wall that rises above the terrace, and which "have never been endangered by the phylloxera." In winter sufficient protection for the plants is afforded by a temporary light shed with sliding panels, which may be opened in propitious weather.

We have received several chestnuts of named varieties from different nurserymen. One of these from the Pomona Nurseries at Parry, New Jersey, is the nut of a Japanese variety, and it is well named Giant from its remarkable size. Mr. Samuel C. Moon sends a sample of the variety Numbo, and Mr. William H. Moon also sends some fine specimens. These nuts vary in quality, but none of them equal in sweetness the nuts on our native trees. The Japanese nut is surrounded by an especially bitter and puckery skin, which can, however, be easily removed. All these big nuts are greatly improved in flavor by being boiled or roasted, and when thus prepared they are almost as good in quality as the American chestnut. There is little doubt that a grove of any of these large varieties would prove a remunerative investment in places where the trees are hardy. It is high time for some of our experiment stations to begin the work of crossing the foreign kinds upon our native stock for the purpose of securing a race of hardy trees which will produce nuts at once of large size and the best quality. Practically nothing has ever been done in the way of developing our native nuts by selection, and no one knows how much improvement is possible until the same care in crossing and selecting is used to produce an ideal Chestnut as has been exercised for generations in perfecting the Apple or the Pear. The nurserymen, who are giving an impulse to nut-culture by calling attention to the possibilities in this direction, are doing the country good service.

The annual report of the superintendent of the Royal Botanic Garden at Trinidad has reached us, and, like its predecessors, contains a large amount of useful information about various tropical economic plants and several interesting and instructive illustrations, the most striking being that of a noble specimen of *Corypha elata*, surmounted by an enormous panicle of fruit estimated to weigh over a ton. Mr. Hart calls attention to the fact that the large crown of leaves borne by this Palm withered and fell flat to the stem soon after the appearance of the huge panicle of flowers. As the fruit set and commenced to develop the leaves became dry, then hung down (as shown in the illustration) and finally fell off, leaving nothing but the crowning panicle of fruit. Mr. Hart remarks: "From the early falling and drying away of the leaves after the period of anthesis, it is fully evident that they cannot assist in any way during the period in supplying or manufacturing the plant-food necessary for the formation and development of the seeds, and that the supplies and material for such purpose must have been accumulated and deposited in an easily assimilated form in the stem itself. This will form an important fact for those who are discussing the movement of fluids in the cells of plants." He points out that morphosis of this character, although rare in temperate climates, is a familiar feature in tropical vegetation. The Silk Cotton-tree, *Eriodendron anfractuosum*, of which a portrait appeared in GARDEN AND FOREST (iii., p. 341), is cited as an illustration of this phenomenon. This tree produces its flowers and sets its fruit at a period of the year when it is entirely destitute of leaves, the seeds being distributed by means of the cotton attached to them just as the tree is putting out the new set of leaves for the season. Mr. Hart, as he has in previous reports, deplors the want of interest taken in forest-preservation on the island, and the inevitable destruction, under the existing feeling on the subject, of the valuable forests which still occur in some parts of Trinidad.

The Catalpa.

THE genus *Catalpa* is eastern American and eastern Asiatic in the distribution of its species. Two of these occur in North America, one in the West Indies, one in Japan and one in the northern regions of China. They are all trees with ample, generally opposite, simple leaves, large terminal panicles of showy flowers, and long, slender, nearly cylindrical capsular pods. The flowers, which appear in all the extra-tropical species in early summer, are characterized by the deeply two-lipped calyx, the irregularly two-lipped, bell-shaped corolla, which is white and conspicuously marked with purple and yellow in the throat, and by two, or rarely four, fertile, and one to three sterile, rudimentary stamens. The capsule is divided into two cells by a partition which is at right angles to its valves. The seeds are numerous and densely packed in the cells of the pod; they are furnished on each end with long, papery wings, cut at the extremity into delicate white fringe.

The familiar species, and the type of the genus as it is now constituted, is *Catalpa bignonioides*, the Catalpa-tree or Indian Bean. It is a low, wide-branched tree, with a short, stout trunk covered with thin, pale, furrowed bark. The wood, like that of the other species, is light brown, and contains numerous large open ducts, which mark the layers of growth. The wood of all the species is remarkable for the thin sap-wood, which consists of three or four layers of annual growth only. The leaves, which emit a disagreeable odor when crushed, are cordate at the base, somewhat acuminate, and are occasionally provided with a pair of salient lateral teeth. They are light yellow-green in color, and do not unfold until nearly all other trees are covered with foliage. The flowers open at the north late in June or during the early days of July; they are produced in very large, compact panicles, and are about an inch or an inch and a half long. They are peculiar in their campanulate corolla, with an oblique limb and entire lower lobe. The inner surface is thickly covered with purple spots and is streaked with yellow.

This tree has much to recommend it as an ornament for the garden. It is hardy; it grows rapidly; it is not very

particular about soil, and insects do not prey upon its foliage. The large, brilliant leaves have an almost tropical appearance, and the flowers, which appear late in the season, when flowers are particularly valuable, are produced in the greatest profusion. There are few trees, certainly, of temperate regions which present a more remarkable floral display than a large *Catalpa*-tree in full bloom. These qualities have made the *Catalpa* one of the most popular trees in all the temperate regions of the world; indeed, it has been cultivated so long, and has now become so completely established in many parts of the southern states, that it is not easy to determine exactly where it grew before man carried the seeds from one part of the country to another.

The *Catalpa* appears to have been first made known to Europeans by Mr. Mark Catesby, the English naturalist, who was in our south Atlantic regions early in the last century and who is remembered by his handsome "Natural History of Carolina," which appeared in London in 1731. He published an excellent figure of the tree, which he says was unknown to the inhabitants of the settled portions of Carolina until he introduced it from the remoter parts of the country. What Catesby meant by the remoter parts of the country is not clear; but it is hardly probable that he ever penetrated more than one or two hundred miles from the coast, and certainly he never crossed the mountains into the region which is now generally regarded to have been the first home of this tree—south-western Georgia, and central Alabama and Mississippi. It is probable, therefore, that the *Catalpa* was first brought east of the Alleghany Mountains by the Cherokees, who are known to have been somewhat interested in plants, and that it was from their cultivated trees or their offspring escaped to the forest that Catesby obtained the plants for the Carolina planters and for his English correspondents, to whom he sent the *Catalpa* as early as 1726. Even to this day there is doubt in regard to the true home of the species. It may be seen growing on the banks of the upper Apalachicola and Flint Rivers in south-western Georgia, so remote from existing habitations that it is difficult to imagine that the seed which has produced these trees could ever have been blown from cultivated plants. Still, it is impossible to surmise how far a plant provided with seed so admirably adapted for transportation by the agency of the wind can eventually be carried from an original starting point; and the fact that the *Catalpa* is hardy so far north, and that it has even become naturalized in some parts of Pennsylvania, seems to be an indication that its true home is not in the hot, low, semi-tropical country of the Gulf states, but rather in some still unexplored mountain region of the Appalachian foot-hills, from which it was early carried by the Indians east into Carolina and south-west into Georgia and Alabama, through which states and beyond it has gradually spread until it is now found over a large area of the middle and southern states.

Two well marked varieties, at least, of this tree have appeared. The first, the so-called Golden *Catalpa*, has bright yellow foliage. The second is a dwarf, compact shrub rarely attaining a height of six feet, but spreading widely, and thickly covered with leaves. This curious plant, which is not known to have produced flowers, passes universally in nurseries as *Catalpa Bungei*, although it has nothing to do with the Chinese species of that name. It is sometimes grafted as a standard on tall stems of the *Catalpa*, and, grown in this fashion, it makes a small tree with a compact round head, useful for the decoration of small gardens and city squares.

The second North American *Catalpa*, *C. speciosa*, was distinguished specifically a few years ago by the late Dr. J. A. Warder, a Nestor among American tree-planters in the west. It is a native of the river-swamps which abound about the mouth of the Ohio and the adjacent parts of Missouri. Dr. Warder's attention was directed to some *Catalpa*-trees planted in the streets of an Ohio town, and found that they grew more rapidly than other individuals planted

with them, and that they assumed a more upright manner of growth. He found, too, that the ends of the branches of these trees were not killed in winter, as was the case with many Catalpa-trees, and that they flowered fully two weeks earlier; that the flowers were considerably larger, and were produced in shorter, fewer-flowered panicles; and that the pods were much larger and nearly twice as thick. These observations led him and several botanists to study these peculiar trees, and it was found that the western Catalpas all differed in these respects from the trees which had been ordinarily cultivated in the eastern and southern states, and that instead of one, North America could boast of two species. It was found, and this is probably true of all the species of the genus, that the wood of *C. speciosa*, although not hard or very heavy, possessed the power of resisting decay in a remarkable manner when placed in contact with the soil. It was found, too, that the young trees grew with astonishing rapidity, and were hardy as far north certainly as the forty-second degree of latitude, and could support the climate and high winds of the western prairies. These were qualities which western planters were in search of, and nurserymen at once set about raising the western Catalpa in great quantities. It has so far proved to be all that was expected of it, and millions of these plants have already been planted in the United States, especially in the west.

The other American species, *C. longisiliqua*, is a large forest-tree widely distributed through the West Indies, where it is prized for its hard, handsome wood, used in cabinet-making, and known as Spanish oak.

The Japanese Catalpa, *C. Kämpferi*, is a smaller and less beautiful tree than either of its North American relatives. It has darker green foliage, smaller and less showily-colored flowers and slender pods. It is no longer a rare plant in American gardens, where it grows rapidly, flowers and fruits profusely, and is perfectly hardy as far north certainly as eastern Massachusetts. An interesting hybrid between this and one of the American species, described in this journal last year (ii., 303), has appeared. It is remarkable in characters intermediate between its two parents, in its hardness, and in its vigorous and rapid growth.

The second Asiatic species, *C. Bungei*, which must not be confounded with the plant found in nurseries under that name, is a native of northern and central China. It is a large tree, with smaller flowers and leaves than those of the American species, and is not yet known in cultivation either in the United States or in Europe. It may be expected to thrive where the Ailanthus will grow; and its introduction into our plantations has long been desired by American dendrologists, who have sought in vain to secure a supply of seeds of this interesting tree.

The illustrations in the present issue display the appearance of *Catalpa bignonioides* as a cultivated plant, and show the unusual method adopted by an old specimen to extend itself by means of rooting branches. Our readers are referred to the account of these venerable trees printed on page 536. It is from the pen of the great-grandson of the man who planted them, and whose descendants down to the fourth generation have been able to watch their growth—an unusual and noteworthy occurrence in this country, where homes are rarely handed down beyond the second generation, and where the children of more than two generations rarely play beneath the shadow of the same trees.

A correspondent of *The New York Journal of Commerce* writes from the White Mountains that he was recently surprised by sounds like distant thunder, which rose at intervals above the steady roar of the October wind in the woods. He was led to make inquiry as to these repeated mutterings and this is what he learned:

Some miles down the valley is one of those glorious mountain torrents which are, or ought to be, the pride of New Hampshire. It comes out of a gorge in the hills, leaping from the shadows of the old forests into the open light of the valley,

with more of spirit and freshness than perhaps any other of all the New Hampshire mountain streams. I am told that the sounds I have heard are the explosions of dynamite and giant powder, wherewith men are blasting out the rocks in this wild river, reducing its freedom to canal-like regularity, so that hereafter the forest-trees which are the glory of Mooseilauke can be cut and sent down stream to market. We have no right to quarrel with the men who are doing this. They own the forests and they own the river, and no one expects them to make a donation of their lumber and their river to the public. But it is now of most pressing importance that the State of New Hampshire should exercise its right of eminent domain and purchase these forests and streams and preserve them. The work of destruction is going on all around the mountains. Timber railroads have been pushed up to and into the ravines on the south and north sides, and now the streams, which, when the destroying work is complete, will cease to flow, are to be compelled by the forces of dynamite to become their own destroyers.

No, we cannot, under ordinary circumstances, complain when a man cuts the timber from his own land, even when he cuts it wastefully. But the forests of the White Mountains have a value beyond the market price of all the lumber they contain, and the wild White Mountain streams have a value beyond their capabilities of floating that lumber to market after they have been subdued to the logger's use. Apart from the function of these mountain forests in regulating the flow of the streams which take rise among them, their highest productive value lies in the charm they lend to the scenery. Even from a material point of view the loss to the state of New Hampshire which the defacement of this scenery would cause, by robbing the region of its attractiveness to tourists, would be incalculable. The native beauty and sublimity of the White Mountains are a source of revenue which will increase indefinitely with an increasing tide of visitors, and it is a short-sighted business policy, not to speak of other considerations, which permits so productive an inheritance to be squandered.

Ornamental Fruits in the Pines.

FOUR species of *Ilex* are now showing their ornamental fruits in the Pines. The Holly (*Ilex opaca*), with its fine foliage, sharp and spiny, and its scarlet berries, is handsome all winter. So is the Inkberry (*I. glabra*), with black fruit and shining smooth leaves. Both are abundant, the latter in all damp places. And the Black Alder or Winter-berry (*I. verticillata*) is everywhere in the swamps and bogs, and still holds its foliage, while the twigs are encircled with masses of bright red berries. Later the leaves will fall, but the berries will remain all winter. The Smooth Winterberry (*I. laevigata*) is also here, but not so abundant as the other species. The fruit ripens earlier and is larger than that of the Black Alder, and is now very bright and showy.

The clustered red fruit of the Flowering Dogwood (*Cornus florida*) is more beautiful than the flowers, and almost as showy. Another species of *Cornus* (*C. sericea*) which grows in wet places has pale blue fruit in flat cymes. This also is quite ornamental. And *Viburnum pubescens* is here, too, with flat cymes of dark purple fruit.

A cluster of the fruit of the Sassafras is very pretty. A fleshy red stem supports the blue berry, making it quite unique. The berry has a sharp, pungent taste, more concentrated than the bark of the root.

The cone-like fruit of *Magnolia glauca* is handsome in all of its stages. At first it is green, and as it matures it takes on yellow and rosy pink hues, and when fully matured the carpels split open and reveal the beautiful coral red, berry-like seeds, which soon drop out of their places, and are held in check by spiral threads which unroll and hold the dangling seeds suspended all around the cone.

Thick tangles of *Smilax* impede our progress. These thickets are terrible, almost impossible to penetrate to any distance—a tangled confusion of vines climbing over shrubs and trees, armed with sharp, stout prickles. But the vines hold pretty clusters of fruit, and one species has coral red berries, but most bear black fruit, some with a bloom like that of the grape, others with shining black berries. A difficult genus it seems to me, all mixed up and as hard to identify as it is difficult to penetrate the thicket.

Above these thickets, growing on old Sweet-Gum-trees, are clumps of Mistletoe, with clusters of pearly white berries.

And the Sweet-Gum has attractive fruit, also—spherical heads suspended by long pedicels on naked twigs, mostly persistent, swaying in the wind throughout the winter. And here is the Ampelopsis, a flame of color, clinging to the rugged trunks of the Gum-trees, and holding clusters of bluish black fruit in reserve for winter feasts for the bluebirds and robins, whose winter quarters are in the great Cedar-swamps of the region.

And the Cedars are now adorned with pretty, berry-like fruit, covered with a glaucous bloom of pale blue. The covering of the seeds is sweet and nice to the taste, and is highly relished by many birds, especially by bluebirds and robins.

The Climbing Bitter-sweet (*Celastrus scandens*) is now displaying its scarlet seeds here and there in the Pines. I found one clinging over an old Cedar-tree which made a charming picture and gave me a hint to go and do likewise in my garden, a result easily accomplished, as both the Cedar and the Bitter-sweet were already there. Not far from this Bitter-sweet the Virgin's Bower (*Clematis Virginiana*) had formed a pretty bower by climbing over some bushes, and, not content with these, it had reached up to a tree, where it displayed its feathery white tails in conspicuous clusters. At a little distance these feathery appendages of the seeds looked like a mass of white flowers.

The Sumach (*Rhus copallina*) is now quite ornamental both in foliage and fruit. The fruit is a dense crimson colored panicle, extremely acid to the taste. And the terrible poison Sumach (*R. venenata*) looks handsome with its scarlet foliage and drooping panicles of white fruit, which I can only admire at a safe distance.

We find plants of the Wax Myrtle (*Myrica cerifera*), with branches almost covered with the white waxy seeds. The foliage and fruit are both fragrant, making it a desirable addition to our ornamental collection. And the Wild Rose hips are abundant and almost as pretty as the flowers. And there are many dry fruits, especially in the Heath family, whose seed-pods are ornamental, such as Andromeda, Leucothoe, Azalea and others.

Turning our attention to the ground, we find in places that it is almost covered with the aromatic Wintergreen, with clusters of sweet, spicy, red berries. And the Partridge-vine (*Mitchella repens*) is creeping around old decaying stumps, showing its twin scarlet berries. And the Wild Cranberry is trailing about in the moss with crimson fruit sour enough to set one's teeth on edge; but the long sprays, covered with small evergreen leaves, and the bright berries, are very ornamental.

Vineland, N. J.

Mary Treat.

Cranberry Culture in New Jersey.

IT often happens that the same crop is profitably grown in different places under different systems of cultivation, and many Cranberry-growers in New Jersey claim that Cape Cod methods are not the best—for New Jersey. I have spent part of two seasons on bogs of the Cape, and have spent a good deal of time for several years past on New Jersey bogs, primarily studying the insect enemies of the Cranberry, but with an eye also to methods of culture. Cape Cod methods are well described by Professor Bailey in the paper quoted in GARDEN AND FOREST (page 511), and perhaps a few words on New Jersey methods, inasmuch as they differ, may prove of interest. The bogs to be cultivated do not differ very essentially from those of the Cape-Cod region. A peat bottom is preferred, and the land once located, dams enough are built to flow it, and the water is left on for a year to kill off the bulk of the vegetation. This is then cut, the brush is uprooted and carried off and the ground decently cleared. The Cape Cod grower would thoroughly remove all stumps, level his bog carefully and sand heavily. This practice has been quite generally followed in New Jersey until a few years ago when some large growers claimed that sanding was unnecessary, and the vines are now generally planted in the mud. Where the vegetation has been killed by flooding, holes are punched in the decaying mass, and vines are set as described by Professor Bailey. It has been noticed that the heaviest crop of berries is borne by vines surrounding stumps, and these are now left in the ground to decay naturally. Ditching and draining are done as on Cape Cod, and old mill-ponds have become favorite sites for bogs.

This method of setting out a bog costs very much less than the Cape Cod method, and the result in looks is very much inferior. The vines, however, grow excellently well, better, indeed, most growers now say, than in sand, and the runners strike root as readily in the mud as they could in any other soil. The weeds are a nuisance, and here our eastern friends have the advantage, for they are more easily controlled in the

sand. However, as the vines cover the ground they drive out most of the other plants, and the stubborn fighters, like Ferns, Sedges and Briars, are gradually exterminated. Some fine Grasses are not meddled with at all. They do not seem to prevent the growth of the vines, and, in fact, are considered rather a benefit, since these grassy patches bear the largest and safest crops. They are less liable to "scald"—the Jersey grower's most dreaded enemy—and they seem protected from many of the climatic difficulties which afflict their cleaner neighbors. A New Jersey bog is never as clean as the Cape bogs, nor usually even as clean as they should be. They bear quite as heavily, however, and after all that is what the farmers are looking for. In the east vines are kept short and re-sanding is done every few years. In New Jersey vines are often allowed to grow until they form a mat a foot thick, and individual vines may be several feet long. In some seasons these vines bear enormously; but they are not so safe for an annual crop as shorter vines. Instead of sanding, many growers mow the vines when they become too rank and so get a new and vigorous growth from old roots.

New England has perhaps the oldest cultivated bog-land, but there are many old bogs in New Jersey as well. Farmers are not entirely exempt from all human weaknesses, and some years ago, when the conviction prevailed that cranberries were a sure road to wealth without much work, Cranberry-land rose enormously in value, and all land was Cranberry-land if it was only in a Cranberry-region. Vines were planted on hill-sides, in sand-holes, in swamps, everywhere in fact. The inevitable reaction came. Insects and other pests eliminated the badly placed plantations and others were abandoned from want of knowledge. I have tramped in rubber boots over bogs on which thousands of dollars were spent which never yielded a dollar, and which now are so overgrown with brush as to leave no trace of cultivation. Naturally, New Jersey is much more favorably located for Cranberry-culture than Cape Cod. Our land is at least equally good, and our seasons are longer. We do not fear frost as early, and our vines get an earlier start. There is not that necessity for looking to early maturity in the berry which has made the Early Black the favorite on the Cape. For color and appearance the Early Black eclipses the ordinary New Jersey berry; but the latter is fully as good in flavor, makes just as good sauce, and has the enormous advantage of keeping well. New Jersey growers usually count on giving the east the early market, sending in only their dark varieties, which sell as Cape Cod berries and at the same price. The bulk of the crop is housed in special cranberry-houses, in which the berries are so packed as to season thoroughly. When Cape Cod berries are out of the way our berries take the market. The color is good, the fruit is usually sound, there is no undue competition, and the berries bring whatever the market will stand.

In describing the separation of berries, Professor Bailey does not refer to "bouncing." In picking late, or over scalding bogs, some soft berries will get into the boxes. To eliminate these, the berries are poured over an inclined screen and allowed to drop on a smooth board, beyond which is the receiver. The sound berries come down with a rush, strike the smooth surface and bound into the receiver. The soft berries come down with a thud, but have no "bounce" in them, and remain on the board, swept off at short intervals by the screeners.

Thus Cape Cod and New Jersey produce the same fruit by quite different means of cultivation; but they are not competitors, for while the Cape has looks and flavor it must sell early, as the fruit does not keep well. New Jersey sells its dark berries as Cape Cod fruit, and keeps its best until the eastern berries are gone and then supplies the market according to demand.

Of late years our growers have paid more attention to developing varieties, but, while they look after size and color, they retain keeping quality as an essential, and the varieties are still too little fixed or cultivated to merit notice here.

The systems of picking are different in New Jersey from those in use on the Cape, but that does not prevent their getting in the berries as effectually.

Rutgers College.

John B. Smith.

I insist upon it that a plan complete in every detail should be adopted at the beginning and followed throughout. To be sure, in certain circumstances I should not hold to this latter point; for, given a fixed leading idea, the artist, during the progress of the work, ought to feel himself free to study his materials anew, . . . to modify his ideas of the details, or even to abandon them wholly or in part in case better ideas should come to him.—Pückler-Muskau.

A Bit of Forgotten History.

OUR valued correspondent, Herr Carl Bolle, of Berlin, recently published in *Gartenflora* an interesting article called "When Did the Weymouth Pine First Appear in Europe?" Weymouth Pine is the name commonly given in Europe to our White Pine (*Pinus Strobus*), and records the well ascertained fact that it was first made generally known in Europe by Lord Weymouth at the beginning of the last century. Specimens were brought to England in 1705, and almost immediately Lord Weymouth devoted himself to the cultivation of the tree, which from that day to this has been extensively planted in different parts of central Europe.

Herr Bolle has no wish to strip the memory of Lord Weymouth of the credit which thus attaches to it. His object is simply to show that, although this nobleman first popularized the White Pine, it had, contrary to the common belief, been seen in Europe much earlier. On general principles, he explains, it is unlikely that its importation can have been so long delayed, for other North America conifers had been introduced much sooner, as, for instance, the Bald Cypress before 1640 and the Red Cedar before 1664. Moreover, there is actual evidence of an early although merely passing attempt to cultivate the White Pine in Europe.

The first modern scientific treatise on conifers is the *De arboribus coniferis, resiniferis aliis quoque nonnullis sempiterna fronde virentibus*, which appeared at Paris in 1553, and was written by Pierre Belon, a physician and a traveler of wide experience. In this book, in the chapter headed "Pinaster," there may be found, suggests Dr. Bolle, a sure indication that *Pinus Strobus*, as well as *Thuya occidentalis*, were already growing in at least one garden of France. Inspired by the maritime achievements of the Spanish and Portuguese, and attracted by the rich fishing grounds of our northern coasts, French explorations of America began early in the sixteenth century. Even sailors were interested by the immense and varied forests of our coast regions, and, although botanical knowledge in the modern sense had hardly yet been born, there was everywhere in Europe a keen desire to find new plants with medicinal virtues. It is recorded that a disease which afflicted, among other less popular patients, Pope Leo X., Francis I. and Ulrich Von Hutten, was treated with a medicine in which sarsaparilla was mingled, with a decoction from the "Canadian Tree-of-life" (*Arbor vitæ*) and other exotic extracts. At this same period navigators were bringing from Canada great packages of a white, very light wood, somewhat spongy in texture and still covered with its bark. This they grandiloquently called the "second Tree-of-life," loudly praising its medicinal properties. After investigating it, Belon pronounced it useless, and, indeed, harmful, as likely to supersede really valuable medicaments. He expressed amazement that other physicians should have allowed themselves to be deceived by impostors to such a point that they had in their turn imposed upon even King Francis himself, and declared the high-priced stuff to be merely "Pinaster wood." By this name is not to be understood what we now call Pinaster, *Pinus Pinaster*, the tree which grows so plentifully on the *landes* of south-western France. But Belon's Pinaster, says Herr Bolle, was a tree which he thoroughly understood and has accurately described—*P. Cembra*, the familiar Pine of Switzerland, and long supposed to be the only European Pine whose leaves grow in groups of five. Misled by the arrangement of the leaves and by analogies of habitat, Belon seems to have thought he recognized this tree again in a small cultivated specimen which was shown him as having grown from seed in one of the royal gardens at Fontainebleau. His description runs as follows: "At Fontainebleau there stands, with evergreen needles, a little Pinaster-tree. When I saw it I recognized it as such at the first glance, by its stem as well as by its branches, its bark and other signs. This specimen has reached man's estate in five years. Its branches stand around the stem in just the same arrangement as on the Spruce and the Fir (*sapino et abiete*), cross-shaped at regular intervals. It has leaves like the Pine but thinner; these stand in bunches, sheathed below in a tube, five or six together and perpetually green. The carefulness of Mother Nature is unmistakably proved by the manner in which this tree buds in spring. That is, it develops five buds (shoots?) at the end of each twig, the central one of which is larger than the lateral ones. From this there then develop further leaves and fruits. By comparing the description of this tree with the tree native to our mountains their identity will be recognized. The specimen at Fontainebleau has not yet borne fruit." Belon then adds that he had collected seeds of *P. Cembra* in Savoy, and obtained plants from them which were identical in appearance with the little tree in the king's garden. To-day, comments Herr Bolle, every cultivator is

familiar with the great resemblance between young plants of *P. Cembra* and of *P. Strobus*. "Nothing is more pardonable than to confuse the two." The little exotic stood unique at Fontainebleau, where, as is well known, the true "Tree-of-life" of the North American provinces was cultivated. By comparison with this it continued to be called the "second Tree-of-life" (*altera arbor vitæ*), probably on account of the fact that their common origin was known, although not specially dwelt upon.

It thus seems probable that it was a White Pine which Francis I. possessed in a living state. Those who question the fact, says Herr Bolle, should consider that Belon's phrase, "thinner" or "very thin leaves" (*folia exiliora*) does not apply to *P. Cembra*, but does in the most decided way to *P. Strobus*.

There were other enthusiastic horticulturists in France at that period who loved to crowd their gardens with novel exotics. But in no record of their collections can the slightest indication of the presence of *P. Strobus* be found. The little tree of Francis I. must have soon disappeared without leaving trace or seed behind. And though the Hollanders, who so long possessed large portions of our country, may well have sent specimens of this striking Pine home to the impassioned horticulturists of their mother-land, no statement of the fact can be found. Pierre Belon's description of the *altera arbor vitæ* at Fontainebleau is the only proof we have of the existence of *P. Strobus* in Europe prior to 1705. But in Herr Bolle's opinion this is enough to carry back the European story of the tree a century and a half beyond the commonly accepted date.

Two Remarkable Catalpa-Trees.

THE tree shown in the illustration (Fig. 68, p. 537) is a Catalpa (*C. bignonioides*), and one of two trees growing on the old P. C. Brooks place in West Medford, Massachusetts. These trees were set out on April 24th, 1809, and owing to their favorable situation have attained a remarkable size. They stand on the south side of the house and are well protected from the winds in winter. Two spouts conduct the water from a large portion of the roof directly to the roots. The tree shown in Fig. 68 is the more interesting of the two. The trunk is nine feet eight inches in circumference at four feet from the ground; it is about forty feet high and has a spread of fifty feet. At four feet from the ground four branches radiate from the trunk, two of which, on the south side of the tree, drop toward the ground until they touch it, and at this point they have rooted and thrown up four or five young shoots, two of which are over three feet in circumference at two feet from the ground. This first rooting of the limbs is but ten feet distant from the stem. The trailing branches extend in various directions over the turf from these first two clumps of shoots, throwing up shoots like huge suckers wherever the old limbs have rooted until a small forest of young Catalpas has been formed under the shade of the parent tree. There is no record of when this peculiar habit first developed, but it must have been many years ago. All the limbs that connect the young tree to the main trunk have been dead for many years, but the wood is still perfectly sound.

The second tree (Fig. 69), standing to the eastward of the one described above, although not so interesting, is a large Catalpa for this region. The trunk is ten feet in circumference at two feet six inches from the ground, and the tree is about fifty feet high and has a spread of thirty feet. A heavy gale took out more than half this tree some years ago. The new branches from the old wound are now sweeping the ground in much the same manner as do those of the sister tree, whose rooted branches cover an area of 300 square feet.

Foreign Correspondence.

London Letter.

CRINUMS.—The genus *Crinum* deserves to fill a much more important place amongst cultivated bulbous plants than it does now. Of the eighty or so species described fully forty are known to be in cultivation, and of these at least a score are possessed of characters sufficiently striking to find general favor. They are not as a rule difficult to cultivate; they flower freely, some species several times a year, whilst their flowers are large, handsome, and almost invariably sweet scented. In England the only representative collections of *Crinums* known to me are at Kew, and in the garden of Sir Charles Strickland, Baronet, at Malton, in Yorkshire. Sir Charles has made a specialty of *Crinums* and several other genera of *Amaryllidaceæ* for many years, cultivating them with conspicuous success, and carefully noting the peculiarities of each under

artificial treatment. He is consequently an authority on garden Crinums. Recognizing this, the Royal Horticultural Society invited him to read a paper on Crinums at the meeting held on Tuesday last. The paper was far too short, considering how little is known of Crinums by horticulturists generally. Still, it served to bring the plants into notice, the drawings of some of the rarest of the species cultivated by Sir Charles affording some idea of the character and ornament of the genus.

Dean Herbert was a keen admirer and grower of Crinums, as may be seen in his book on *Amaryllidaceæ*, wherein forty-six species are described, almost every one of which he appears to have had in cultivation. He also describes no less than twenty-three hybrid Crinums, the number being soon increased to thirty-two according to Sweet's "British Flower-Garden."

A very remarkable fact, and one which intending breeders of Crinums should make special note of, is the statement made by Herbert that "all the hybrid Crinums raised between *C. Capense* and the tropical species are hardy enough to stand out-of-doors against the front wall of a stove, where, if a mat is thrown over them in sharp frosts, they preserve much of their leaves through the winter, and from May to November continue throwing up a succession of flower-stems in great perfection." The only hybrid Crinum known in gardens now is *C. Powellii*, which was raised in England about fifteen years ago by crossing *C. Capense* and *C. Moorei*. The result of this cross was the production of at least two well marked varieties, one with pure white flowers, the other with exquisite pink flowers. This hybrid is perfectly hardy in England. It has handsome semi-erect foliage, stout flower-scapes, four to five

Fig. 68.—A Remarkable Old Catalpa-tree.—See page 536.

Herbert succeeded in making such crosses as *C. Zeylanicum* with *C. Capense*, *C. pedunculatum* with *C. Capense*, *C. scabium* with *C. Capense*, *C. rubescens* with *C. Capense*, *C. speciosum* with *C. deflexum*, etc. He found that all Crinums, however dissimilar, readily intermix when brought together by human agency, and that it was only in cases of constitutional discrepancy, as, for instance, when a moisture-loving species was crossed with one which affected dry treatment, or a tropical species with one from cool regions, that the progeny of such crosses were not fertile. It is therefore surprising that not one of the hybrids mentioned by Herbert and Sweet are in cultivation now.

The first hybrid Amaryllid raised was *Hippeastrum Johnsoni* from *H. vittatum* and *H. regium*, and the second was *Crinum Goweni*, from *C. Capense* and *C. Zeylanicum*. This was raised by the Earl of Carnarvon at Highclere in 1813.

feet high, each bearing a bunch of from twelve to sixteen flowers, which are larger than those of the Belladonna Lily, and as elegant in form. The white variety has shorter scapes, but the flowers are fully as large as the pink ones, and they are of the purest white. Planted in a deep, well manured soil, in a sunny position, this Crinum increases rapidly. Mr. Gumbleton planted a single bulb which in seven years increased to about twelve, which pushed up eighteen scapes, averaging four feet in height, each bearing a huge bunch of beautiful flowers of the greatest value in the garden or when cut and placed in water. If some skilled cultivator and breeder would but take the Crinums in hand he would almost certainly produce the most valuable results in a comparatively short time. The material is at hand, its plasticity has been proved long ago by Herbert and others, whilst as an example of what may be expected we may point to the hybrid raised by Mr. Powell,

which is now admitted to be one of the most beautiful and stately bulbous plants known.

In the species themselves there is much that deserves admiration. There are thirty-five in cultivation at Kew, and of these only about one-fifth are what one would call difficult to manage. The easiest to grow and the most gigantic are among those species which do not lose their leaves annually and require plenty of water all the year round. *C. Asiaticum*, *C. deflexum* and *C. pedunculatum* have large bulbs with very thick stem-like necks, leaves four feet long by from four to six inches in width standing out like the leaves of Fourcroyas. The individual flowers of these species are comparatively small, but they are borne in great numbers on stout, erect scapes; they are white with red tinged stamens, and are very fragrant. *C. angustum* and *C. amabile* are almost as large as the first named in leaf and habit, whilst their flowers are large, deep rosy red and deliciously scented. Then there is *C. giganteum*, an excellent plant for stove borders, flowering freely, the flowers pure white, six inches across, with broad, spreading segments. *C. Careyianum* is like it, while in *C. podophyllum* we have its dwarf representation. The large flowered *C. Zeylanicum*, *C. Kirkii*, *C. latifolium* and *C. scabrum* are as easy to cultivate as Eucharis, and their many flowered heads are common ornaments in the stoves at Kew. They have somewhat urceolate flowers six inches long by about four broad at the mouth, and they are white, more or less tinged or streaked with crimson.

Distinct from all the foregoing in the form of their flowers, which are erect, with tubes six inches long, narrow, long, radiating segments and anthers standing erect, are the species of the section called *Platyaster* by Baker. Of these we grow *C. Hildebrandtii*, white; *C. erubescens*, deep crimson; *C. Americanum*, *C. Commelyni*, *C. angustifolium*, all white; *C. amœnum*, and the rare *C. purpurascens*, from west tropical Africa. This last named is said to be almost wholly aquatic in its habits. We find it likes abundance of water and a tropical temperature; with these it grows very freely, sending out its long stolon-like suckers from the base of the bulb in every direction. *C. brachyneura* has the most beautiful snow-white, waxy flowers, in umbels of about twenty on scapes a foot long; each flower is three inches across, the segments overlapping, as in the Zephyr flower, and the stamens only just showing above the narrow tube. If this species would but behave a little better under cultivation it would deserve to rank amongst the first half dozen stove bulbs. It is a native of Bombay, from whence it was introduced and flowered at Kew thirteen years ago. It has recently again been brought into prominent notice.

C. Moorei is one of the noblest of our greenhouse plants. Its stately scapes of large rosy flowers are scarcely ever absent from the conservatory in summer. Out-of-doors the common African species *C. Capense (longiflorum)* is quite at home, flowering and fruiting abundantly all the summer through.

Rose Notes.

JEAN DUCHER is a pure Tea Rose, sent out in 1874, that notable year in our Rose calendar, which also gave us Perle des Jardins and Marie Guillot. Jean Ducher is one of those exquisitely colored Roses which captivate the eye at once, a soft, silvery salmon, with heart of glowing, rosy peach. It has not been sufficiently experimented with in our country to be thrown aside, though it must be confessed that under ordinary treatment it does not open its buds well with us. Its very attractive coloring should win for it a more careful trial.

Another beautiful Rose in this same line of rich coloring is Princess Beatrice (Tea), which proved such a lamentable failure as a forcing variety, but which, we believe, has never had a careful enough trial as a border Rose. Its foliage, habit and good constitution would all point to it as an ideal bedder, while its coloring is as unique as it is beautiful.

And speaking of fine bedders, probably no Rose is quite so perfect in this line as the lovely white Tea, Marie Guillot, mentioned above. So long as fine white Roses are as highly appreciated as at present this grand variety should be planted in profusion. Its flowers are very double and of a most beautiful clear white shade just touched with lemon, and very easily produced.

Ethel Brownlow (Tea) produces a bud and flower too small for popularity in our country; doubtless if it were carefully thinned out and only a few buds allowed to the plant, as is usual in England, it would make a better showing, as it cer-

tainly can be seen in fine form across the water; but with us it is a very slim, straggly grower.

Rubens (Tea) is an extremely fine white Rose, quite similar to its parent, Devoniensis, save that the bud is not quite so long as in that variety. It is more double, too, and a stronger grower; it can be found growing in many a garden under the label "Devoniensis," for it has been sent out in place of that variety in a great many cases, being so similar to it, and the dealer has doubtless excused himself by the thought that he was sending "something really better than was ordered." It is an early bloomer and a grand Rose in every way.

I am asked if there is any better white hybrid Perpetual than Merveille de Lyon. We believe it to be unsurpassed, though White Baroness is probably as good, and Mabel Morrison has only an occasional touch of color to mar its pure whiteness. These three white hybrid perpetuals and Baroness Rothschild (pink) are so absolutely perfect in form and color and texture that they can never be outdone in these respects. But in our northern and western country they are next to useless as outdoor Roses, owing to their liability to attacks of what florists call Black Spot, a fungoid disease fearfully prevalent among Roses grown in the open air.

When a Rose begins to drop its leaves and shows brown spots on their surfaces, we know that the Black Fungus is present. Scientific investigation has proved that the tissue between the upper and lower surfaces of the leaf is the point attacked, hence the difficulty of applying any solution effectively. We believe that nine-tenths of all the failures in Rose-growing in the sections named are due to this scourge. With all our investigations and experiments no remedy has as yet been found that will successfully check its development in the open ground. Sudden changes in temperature, excess of moisture, or the lack of it, seem to cause its development. Like other insect or fungoid pests, it will doubtless run its course and disappear, and there are even now indications pointing in this direction. It is a very fortunate thing indeed that many of the hybrids are of strong enough constitution to be able to withstand its attacks, though the very finest varieties seem to succumb first, and were it not for the fact that this disease is pretty well under control in our greenhouses, we should no longer be able to show perfect blooms of Baroness, Merveille de Lyon or of their very aristocratic sisters.

We have been very glad to discover a rather new variety, quite as fine as the four referred to, not absolutely white, but very delicately tinted pink, which, so far, seems proof against black spot. This variety is Madame Joseph Desbois, sent out by Guillot in 1886, a strong, free-growing variety, carrying superb blooms, very fine in the open air.

Heinrich Schultheis (a cross between Mabel Morrison and E. Y. Teas) was sent out by Bennett in 1882, and is a grand Rose in every respect, a strong grower, bearing large, double, sweet flowers of a delicate rose shade. It should be much more extensively grown in our country.

Our Madame Georges Bruant, planted two years ago in the open ground, has been in fine condition during the season, and shows no signs of mildew. It bears its flowers in about four crops, the first bloom, of course, being the most profuse. We value this Rose highly, and think that as it becomes established it loses its liability to mildew. Its clusters of immense snow white flowers are very distinct and beautiful.

Notes on Shrubs.

THE common Dwarf Chestnut or Chinquapin (*Castanea pumila*) is a plant rarely met with in cultivation at the north, though it possesses qualities rendering it desirable both for ornament and utility. Its extreme northern limit of spontaneous growth is given as southern Pennsylvania and Ohio; but when transplanted to the region about Boston it is quite hardy and seems to find a climate well suited to its requirements as regards healthy growth, although it does not attain large size. Well established plants never show the least injury in the most severe winters here.

In its most favorable southern and south-western home the Chinquapin sometimes becomes a small tree and grows to a height of forty or forty-five feet, with a stem from one to two feet or more in diameter, so that its timber is of use for posts, fencing, or even for railroad ties. In sterile or exposed situations, or when it is brought north out of its natural habitat, it appears to be in about its best period of growth and development when from five to eight feet high, at which time the spread of the branches is usually greater than the height, as a number of stout stems usually arise from the same base at the root. The habit of growth of the plant is very similar to that

of our native Hazel-bushes, so well known in the north-eastern part of the continent, and hardy enough to be indigenous quite far north in Canada.

The branches of this little Chestnut are usually well covered with foliage of a rather light green color. The leaves are smooth, shining above, and covered with a smooth grayish down or tomentum beneath. In general contour they resemble those of the common Chestnut, but they are shorter, being only from three to five inches long, and they are less acutely pointed and are broader in proportion to the length. The yellowish white staminate blossoms appear in much profusion at

the nuts fall to the ground, and, if the atmosphere or ground is moist, they at once begin to germinate and put forth a radicle. Indeed, the propensity to germinate is so great that the nuts often sprout before they fall, and, as they do not long retain their vitality, they cannot be transported for planting in distant places unless packed in soil or other material which will prevent too fast drying. The difficulty of transporting the fresh seed while it retains its vitality has no doubt been a factor in preventing the wide and general dissemination which the plant seems to merit. The nuts, though small, are sweet and of good flavor, and the plants are quite prolific and usually bear

Fig. 69.—The Catalpa-tree (*Catalpa bignonioides*).—See page 536.

about the same time as those of the common Chestnut at the end of June or early in July, and at this time these Chestnut-shrubs present quite a pretty appearance when massed together. The blossoms are followed by the clusters of light green involucre, or "Chestnut-burs," which reach maturity about the 1st of October, when they open and disclose the smooth, shining, dark brown nuts.

The nuts of the common Chestnut are usually borne two or three in a bur; but those of the Chinquapin are produced singly, so that their sides are not flattened, and they are only about half the size of chestnuts. Soon after the involucre open

freely every year. By care and selection larger and finer flavored nuts than the average might easily be obtained. It seems possible that this Dwarf Chestnut might thrive in higher latitudes than this, in places where the Chestnut-tree will not live, and especially in regions where winter snows are generally deep.

The Japanese *Photinia villosa*, which was figured in the first volume of GARDEN AND FOREST (page 67), is very handsome when in full fruit, although perhaps not more showy than some species of Hawthorns or of Crab Apples at this season. The serrated, stiff, thick, dark green leaves generally cover the

branches well, and the many-flowered corymbs of Hawthorn-like blossoms, which are produced in the first or second week of June, are quite showy. On well established plants the fruit is produced in corymbs, but it is often borne singly or not more than two or three together when the plants are young or in poor condition, or when the flowers have suffered injury. It does not ripen until the middle of October, when it turns to a shining deep red or scarlet color, and remains in a bright and showy condition for a considerable length of time. When fully ripe it is of a sweet and pleasant, though somewhat insipid, flavor. It is of an oblong shape and about a third of an inch in length, much resembling the drupe-like pomes of some of the Hawthorns. The fruit itself, however, is more like that of the Juneberry (*Amelanchier*), the pulp being granular, soft and of a yellowish color, containing commonly only one, but sometimes several, large, brown, thin-coated seeds, enclosed in a very thin and fragile core.

This is another fruit which might be made useful as food if selected and improved by cultivation.

The plant known as *Pourthia arguta*, from the Himalayas and other portions of Asia, which there is not sufficient good reason to separate from the genus *Photinia*, produces fruit having a very close resemblance to that of *Photinia villosa* in form, color, flavor and texture. It ripens at the same time, although the blossoms appear about a week earlier. The color of the fruit is perhaps of a clearer, brighter scarlet than that of *Photinia villosa*, but it has not as yet been produced so abundantly on plants here. The habit of the plant is much lighter and less stiff and rigid in foliage and limb. Both apparently become large shrubs or little trees, varying in habit according to circumstances like our native Shad-bush or Juneberry.

Arnold Arboretum.

J. G. J.

Some Native Ferns.

OF the four or five Spleenworts native to New England which are useful for out-door culture, *Asplenium thelypteroides* is an important member. Its average height is about two and a half feet, and the fronds are six or eight inches wide and twice divided. Several of these nearly erect fronds come from a thick and usually forked root-stalk. It is often found in moist, shaded ravines growing with the narrow-leaved Spleenwort (*A. angustifolium*) and *Aspidium Goldianum*, but is more common than either of these. It is sometimes found in open sunlight, and in a soil which never becomes too dry it might be grown in the sun. It likes a rich, peaty soil which is always moist, but not too wet. In this it resembles many other Ferns that require constant moisture about their roots, but will not live in a wet place. The best time for transplanting is early spring, or in autumn if slightly protected the first winter. It may not make a good showing the first year, but it will soon become well established if placed in a suitable location.

Aspidium Boottii grows two feet high, with narrow fronds, on stems about half the length of the frond. It seems to grow in a peaty or boggy soil in thickets. Transplanted into a fine loam, with a mixture of peat added, it thrives finely. A heavy soil would not suit, nor would it stand a dry location. It needs shade, or partial shade, and may be transplanted in either spring or autumn.

We have in North America three species of Bladder Ferns, two of which are native to New England. Both of these are very useful for cultivation in certain localities and are among the easiest kinds to transplant. The larger *Cystopteris bulbifera*, which is common in shaded ravines, and also not rare under low shaded cliffs, is a graceful plant in midsummer, when the fronds are just matured. Its height is about two feet, and the fronds are only three or four inches wide near their base and taper to a point. But the fronds are not durable. They turn brown earlier in autumn than in most species. It propagates itself chiefly from little bulblets, which form on the back side of the rachis of the frond. These fall, take root and form new plants. A few plants set in a moist, shaded soil soon form a dense bed.

The other species, *C. fragilis*, is even more delicate and slender than the first. It is one of the first Ferns to start in spring, and its fronds die early. Even in August it is sometimes hard to find the roots, because the fronds have dried up so that they are scarcely visible. It is a common Fern on shaded cliffs and varies much. The fronds are oblong-lanceolate in shape, and grow from six to ten inches high. Both of these Ferns grow in tufts, several fronds to a plant, and have small roots for the size of their fronds. It is valuable for the rock-garden or for planting on cliffs.

The common Grape Fern, *Botrychium Virginicum*, may be

found in almost any rich woods of New England. About half way up its stem the plant divides into two segments. One, a sterile frond, is sessile, somewhat triangular in outline, of a thin and delicate texture and three or four times divided. The other, which is the fertile portion, is long stalked, and is a close, narrow panicle or frond two or three inches long by an inch or so wide. When this fertile portion has just matured it makes a pretty plant. The two parts, though quite unlike, are both very handsome. But the fertile portion is of short duration. It soon sheds its spores and withers, and even the sterile frond, though lasting usually some time after the fertile one has decayed, is of much shorter duration than that of most Ferns, for by the last of August it has usually disappeared. It is an easy Fern to grow in any ordinary rich soil in the shade, and while it lasts is one of the handsomest.

Southwick, Mass.

F. H. Horsford.

Autumn Crocuses.

THE Colchicums, usually known under this name, are too rarely seen in cultivation, as I was recently reminded by seeing in a Massachusetts garden beautiful clumps of the pure white variety of *C. autumnale*, covered with dense masses of snowy flowers. *C. autumnale* itself is of a pretty pale lilac purple, and contrasts well with the pure white variety. These plants are also known as Meadow Saffrons, owing to the fact that the anthers of the flowers of *C. sativus* furnish the Saffron of commerce. The roots also (which would appear at first sight to be bulbs, but are really corms), together with the seeds when dried, produce the drug known as Colchicum, which, though very poisonous, is a valuable medicine. *C. autumnale* is common in some parts of Britain. I well remember seeing it covering acres of meadow land with a pretty purple tinge in the autumn months, but it is probably exterminated there in that locality now, for an enterprising local firm were busy collecting the corms. Besides the two single-flowered forms of *C. autumnale* above noted, there are also double forms of both which are very beautiful, but also rare and seldom seen in catalogues, at least in America, where, indeed, it is not an easy matter to find Colchicums, for though I obtained not long ago a dozen bulbs of what were supposed to be the type, half of them proved to be white flowered.

C. speciosum is a very fine species, but so far as I can learn no one seems to have succeeded with it here in the eastern states. This plant is much larger than those already named, and of a crimson-purple color; it is, in fact, the largest of a very beautiful genus. I have never yet seen it in the bulb lists, so it is hard to find out whether it is possible to grow it or not. All the varieties of *C. autumnale* thrive well in a good, well drained soil, but should the soil be of a retentive nature they would require a liberal addition of sand. They would thrive admirably on rock-work, where they could push through other plants of a prostrate habit, for the Colchicums flower in fall; the leaves appear in spring, and about midsummer die off and the roots have a season of rest. Imported roots usually commence to flower on the voyage, and the flowers are very liable to get bruised. This, however, will only affect this season's flower; and they will probably start away all the stronger in spring for having been relieved from producing and maturing the quantity of flowers that each root produces when established.

South Lancaster, Mass.

E. O. Orpet.

Vanda Sanderiana.

AMONG the fifty species of Vanda that are known to botanists *V. Sanderiana* may be considered as the king of them all in many respects. Perhaps it has a close rival for this honor in *V. Hookeriana*, a plant so completely distinct from it in every way that one might easily be pardoned for imagining that it did not belong to the same genus. Indeed, the question whether *V. Sanderiana* was not really an *Arachnanthe* or an *Esmeralda* instead of a Vanda has been broached; but as it is usually considered to belong to the latter genus I cannot do better than conform to the general opinion.

V. Sanderiana produces stems from one to four feet high, and these are furnished with distichous, narrow, strap-shaped, recurved leaves, leathery in texture, and more or less deeply and obliquely cut at the apex. Plants which possess remarkably pretty flowers do not always produce them so freely nor so often as one would like. This Vanda, however, when well grown flowers very freely. The strong, stout peduncles are developed from the axils of the leaves, and have been known to bear as many as a dozen flowers at a time. In September I saw a plant not more than nine inches high bearing eight flowers on a peduncle; and since the individual blooms often measure four and five inches across vertically, and almost the

same horizontally, one may imagine what a splendid spectacle a large spike of this species offers. One of the chief characteristics of the flowers, and one which has reminded many of the flowers of *Miltonia* (*Odontoglossum*) *veixillaria*, is that they are flat, the sepals and petals being almost in the same plane, the lip alone projecting. The upper sepal and the two petals are almost similar; the former, however, being larger. They are roundish oval in shape, of a soft pink or lilac color, and decorated at the base with crimson spots. But it is the two lower sepals which form the chief attraction of the flower. They are much larger than the other segments and broadly elliptic. The ground color is a soft creamy yellow, becoming more subdued toward the margins, and upon this there are from seven to nine broad red veins, half of which give off branches toward one edge and half toward the other, thus giving the whole a most charming appearance. The projecting front lobe of the lip is dark brownish red with three keels in the centre, while the ovate side lobes are greenish yellow speckled with red, and the short, thick column is of a bright, conspicuous yellow.

A variety known as *Albata* appeared about four years ago in the collection of Mr. W. Lee, of Downside. It has smaller flowers, with white upper sepal and petals, which are spotted with purple at the base, where the petals also have a sulphurous tinge. The lateral sepals are yellow, with a white margin, and reddish feathered veins.

Vanda Sanderiana itself has only been about seven years in cultivation, having been introduced in 1883 from the island of Mindanao (the largest of the Philippines) by the firm in honor of whose chief at St. Albans it received its name. So great was the sensation caused by its appearance that at the London salesrooms in October, 1883, as much as 200 guineas were willingly paid for a plant less than three feet across and bearing ninety leaves. And as evidence of the great esteem in which Sander's *Vanda* is still held, I may mention that in September of this year Sir Trevor Lawrence paid ninety guineas for a plant imported by the same firm. Mr. Lee, of Downside, who a few years ago possessed one of the finest collections of Orchids in the world, had the honor of being the first to flower this *Vanda* after its introduction.

Imported plants must be carefully treated at first in order to establish them. They should be put in a warm, moist house, spread out on the stage until the leaves and growths begin to "plump" a bit. Or they may be put in pots, with clean crocks around the roots, and receive an occasional syringing until the same effect is produced. When thoroughly established they should be put in a compost of peat and moss, with which may be mixed pieces of crocks and charcoal. In spring-time growth begins, and as it increases in vigor water must be given in proportionately larger quantities. The temperature during this period may range from sixty to eighty degrees Fahr., and the atmosphere should be laden with moisture. Abundance of light without exposing the plants directly to the sun is also necessary, as it not only accelerates the growth, but also ripens the plant. A short period of rest may be given the plants in winter, but they must not be permitted to get dry, and the temperature may vary from sixty to sixty-five degrees Fahr.

Setting Strawberry Plants in Autumn.

ORDINARILY I have not advocated fall planting to any great extent, as spring-set plants generally succeed the best; but this season has been exceptional, and those who have planted early in this section are fortunate, judging from my own experience. Last spring the ground which I had intended for strawberries was in peas, and I set only a few plants of several varieties for stock, and my fruiting beds were turned under as soon as the crop was gathered. This left me to depend on fall-set plants for my strawberry-crop next season, and as soon as the peas were harvested the ground was prepared and ready for the plants before the plants were ready.

About the middle of August the ground was set with 500 plants of the newer varieties, and as they were lifted and transferred to their new quarters with a mass of soil attached to the roots so few of them felt the change that the loss was less than two per cent. Such plants, with their roots running through the soil in a natural way, are altogether superior to potted plants. These plants were set in rows two feet apart, and they have grown and thrown out such strong runners that, if left undisturbed, I believe they would have covered the entire surface of the ground before winter. Rains have been frequent, keeping the ground wet and cool—just the conditions needed for them—and they have improved the opportunity, and offer a better promise of a crop than I have ever seen in

fall-set plants. By the middle of September the bed needed attention, but when the work should have been done the ground was too wet, and the plants were left to care for themselves while the grape harvest was gathered.

The bed has just been cleared up, the runners and surplus plants removed, and the prospect is fair that they will grow yet for some weeks. I estimate the gain in setting such plants from one's own grounds as fully fifty per cent. over plants brought from a distance whose roots are divested of soil. If persons who wish to follow peas or early potatoes with strawberries would adopt this plan of setting a few plants early in spring for stock, they can generally set their new beds much earlier than if they depend on buying their plants, can have better plants and better results, but, as stated at the outset, it must be remembered that this has been an exceptional season. With hot, dry autumns, as we sometimes have, the results would be far less satisfactory.

Earliness in setting in spring or fall is the keynote to success. Stock plants set early in spring before growth commences receive little or no check, and will furnish plants for fall setting much sooner than if planted later, and the earlier plants are set in July or August the more satisfactory will be the results. Dealers do not like to sell plants before September on account of the loss of young plants, and for this reason the price of fall plants should be double that of spring plants. I have another bed set between the 2d and 7th of September which has done fairly well; but just at that time we had a week of hot, dry weather, and the plants were checked, mainly because they could not be lifted with the earth adhering as in the former case.

Grapes in Eastern Massachusetts.

WE cultivate in our experimental collection fifty-five varieties of hardy Grapes, one vine of each, and in order, if possible, to ascertain the best varieties for family use, we have given them careful personal attention. The following, ripening in the order named, are the twelve most approved by my family: Lady, Moore's Early, Cottage, Eumelan, Worden, Wilder, Barry, Brighton, Massasoit, Lindley, Prentiss and Iona.

Lady Washington, Jefferson and many others are good, but only ripen when the growing season is longer than the average. We are located on the highest land in the city, eighty feet above sea level, with grounds protected by a six-foot, tight board fence on north, west and south, also on the north by a belt of Fir and Pine-trees. Up to the present time, October 20th, there has been no frost in our grounds. Three weeks since it appeared in the valley 500 feet north of us.

We prefer a wire trellis running north and south, with posts ten to fifteen feet apart, six feet high, and carrying five courses of wire, about equal distance apart, stretched horizontally and fastened to the posts. The vines are set eight to ten feet apart in rows eight feet apart. Although they are hardy, in our changing climate we find they do better if laid down after pruning in November and covered with earth. The fan-system of training, and the spur-system of pruning, we consider most satisfactory. The limited area of our grounds, being a city lot, made it necessary to utilize every foot of land. It is under-drained and subsoiled. The only fertilizers we have used are cow-manure, ground bone and wood ashes.

Benjamin G. Smith.

A Dangerous Enemy to the Radish.

A LARGE grower of Radishes in Piscataway, New Jersey, tells me that he will be forced to give up raising this crop. His favorite sort is a mammoth white. Half of the crop or more has been ruined this season. Before the roots are a quarter of their marketable size they turn black in spots, where they shrink and often crack. An expert can go through the rows and identify the diseased roots by the peculiar yellow color of the foliage. A microscopic examination of the diseased places on the roots reveals the traces of the same Fungus, or one very closely related to it, which causes the "club-root" of the Cabbage and the "knot-root" of the Turnip. All three of these host-plants belong to the same natural order (*Crucifera*); and it is not surprising to meet with this Fungus in the roots of the Radish. Several complaints have come to the station of fields of Cabbage ruined by the "club-root." This is so named because the Fungus of a very low order causes the Cabbage root-system to become a mass of irregular, misshapen warts and knots. With the Turnip the root is more fleshy, and the opportunity for distortions is not so great. Under the microscope there are no filaments to be seen, and therefore this Fungus differs from nearly all others which prey

upon plants. About all that can be seen is a cell of the root tissue, here and there, packed full of very minute spores. In the Radish the dark portions of the flesh, which is somewhat mottled or marbled, are close around the spore-bearing cells.

It is a well known fact that when this *Plasmodophora* once gets into the soil it remains for some time, and it is not safe to grow Cabbages soon again upon infested land. In case of the Radish failure it is probably true that the land was first "seeded down" with the Fungus spores which were produced in Cabbage, as that is the plant most frequently infested with it. The land in question has long been a truck-farm, and Cabbage is one of the leading crops.

These Fungi that thrive under ground upon the roots of plants are not easy to reach with remedies. The only practicable way seems to be the abandonment of the plants subject to the attack, and in a few seasons the germs will starve to death.

Rutgers College.

Byron D. Halsted.

Adlumia cirrhosa.—This interesting and delicate plant, known by the common name of Climbing Fumitory, is hardy in this section and westward. It is biennial, and in favorable spots sows its own seed, and thus can be treated as a perennial. For covering bowers, trellises, etc., it is admirable, as, catching with its slender young leaf-stalks upon anything it can fasten to, it soon covers a shrub or trellis with its delicate foliage. It is sometimes called Allegheny Vine, and erroneously Mountain Fringe, as it is found in wet woods and delights in shade and moisture, although it will grow in open places. I find it most useful when treated as an annual, as it has no appearance of a vine or tendency to climb during its first year, while its thrice-pinnate leaves and delicate leaflets have the appearance of a Maidenhair Fern, although of a lighter color. It is of rapid growth, and most useful for decoration in the place of these Ferns where they cannot be had. It lasts longer in a cut state than the Fern. Early in the second season it starts its climbing growth, with little to remind one of its appearance the first year. It is then of little use for cutting, and where plants are required for this purpose it will be necessary to sow the seed early every year and thin out or transplant the seedlings, giving each plant room in which to develop.

Correspondence.

The Palms of the Southern California Border.

To the Editor of GARDEN AND FOREST:

Sir.—The identity of the Washingtonias which grow on both sides of the southern boundary of California is somewhat uncertain. Those of the cañons of Lower California and those of the desert on our own side of the line have both been supposed to be *W. filifera*. This species was described from plants raised in Europe from seed whose source was not definitely stated. Long after a second species, *W. robusta*, was described in the same way, the seed being said to come from California. No native tree has yet been found which could be referred to this species. It has even been suggested that it was a mere gardener's variety, a view which finds some support in the insufficient characters assigned to the species.

Mr. Watson, however, who has seen both of these Palms at Herrenhausen, and has them in cultivation in the Botanic Garden at Cambridge, is inclined to consider them distinct, and his opinion is certainly entitled to great weight.

The question then recurs as to the true habitat of *W. robusta*. Mr. Watson has learned that the original source from which European seedsmen were supplied with seed of Washingtonia was the Cantilles cañon in Lower California, while later, and a few years before *W. robusta* was proposed by Wendland, collectors began to obtain their seed from the more accessible groves in the desert south of San Bernardino. From these facts he suggests in a recent contribution (*Pro. Am. Acad.*, xxv., 136) that the Palms of the former place may be the true *W. filifera*, while those of the latter may be *W. robusta*.

Should this supposition prove true *W. robusta* would be the proper name for the only Palm known to grow within the limits of the state of California. It cannot be accepted, however, until a careful study and comparison of the trees of the two regions shall have been made by some competent botanist, which may be rather hoped than expected.

Mr. Watson and other writers call the California tree the "Palm of San Bernardino County." In point of fact, not a single indigenous Palm is known to grow in that county. They are entirely confined to San Diego County. The error is a trifling one, but may be corrected in the interest of accuracy.

San Bernardino, Cal.

Samuel B. Parish.

The Quality of Russian Apples.

To the Editor of GARDEN AND FOREST:

Sir.—As my friend, Dr. Hoskins, of Vermont, has objected, through the columns of your paper, to my opinion of the Russian Apples expressed at a meeting of the Pomological Society at Lewiston, Maine, last month, perhaps I ought to say that no one has a more sincere desire for the success of the Russian fruits in the northern part of the United States than myself; but it certainly is my duty to express my honest convictions, especially when called upon by direct question as at that meeting. It would be both unfair and unwise to pronounce any judgment that was not based on positive knowledge, or to give utterance to "a hasty and immature opinion." I have known some of the varieties mentioned, such as Oldenburg, Red Astrachan and Alexander, since my childhood, and I am free to say I rarely ate one from the very fact that there were so many other varieties that suited my taste much better. No doubt if I had lived in northern Vermont, or some other region where the choicer varieties of the Apple do not succeed, I should have relished even a half-ripened Red Astrachan.

That Russian varieties are grown in many of the orchards in the true Apple-growing region is a fact, but it is also true they are grown to a very limited extent, except in the north. Who plants an orchard of any of these varieties elsewhere?

When I speak of the Apples in question I can say practically the same of all the Russian varieties with which I am acquainted, and I have had the opportunity of testing at least thirty or forty of the varieties most prized; nor has this judgment been formed in the office alone, where samples of them are almost daily received during the fall. From the meeting in Maine I went directly to the home of Dr. Hoskins at Newport, Vermont, and I was greatly pleased with what I saw of Russian apples in his orchard. Trees of some of the newer Russian varieties were heavily loaded with fruit of handsome appearance and fair quality, although none of them would rank as dessert apples with Primate, Jonathan, Grimes' Golden, Hubbardston and many others with which nearly every pomologist is acquainted. But it is only fair to say that in the same orchard trees of Wealthy, Iowa Russet, Magog, Red Streak, Scott's Winter and other American varieties were loaded equally well, while in quality the fruit excelled that of Russian varieties.

I have no prejudice against Russian apples, and so far as the extreme north is concerned, I now say they are superior to most American kinds in the matter of hardiness. But from northern Iowa I have lately received fourteen native varieties of winter Apples from one man; all are seedlings of fair quality and good size and appearance. From Wisconsin and Minnesota there have also come apples of good quality and some that will keep until late in the spring. It is winter apples that the north now needs most. Dr. Hoskins has sent me specimens of his apples this fall, and I was much pleased with the appearance of them, but I did not find them of superior quality. Nearly all of them were very light, not heavier than Fameuse, and greatly lacking in saccharine matter, although they would be good for cooking purposes. Prolific Sweeting, which I saw bearing abundantly in Dr. Hoskins' orchard, is very pleasantly flavored, but not so rich as many of the sweet apples; however, it is to be commended in the north on account of its hardiness.

When specimens are received in this office they are not cut on sight, but such as are not mature are kept until they are ready for testing. It is no doubt true that the locality in which the varieties are grown has considerable influence on their quality. A Ben Davis grown in Maine is about worthless, as I have had ample opportunity to judge, while the same variety grown in Arkansas is large, handsome and fairly well flavored. It would be unfair to compare any variety with Ben Davis in Maine, because it is not suited to that locality; and it would be equally unfair to compare any variety suitable to the north to a Ben Davis grown in Arkansas.

The cooking qualities of an apple are important, as Dr. Hoskins says; but if we can get an apple that is rich in saccharine matter there is usually no reason why it will not cook as well as one which is "thin" and needs sugar added to give the sauce richness. An apple is no richer for having been cooked, although it may be more palatable. If a Hubbardston or Esopus apple were cooked and compared with a Red Astrachan and Alexander the difference in quality would be as clearly perceived as it was before cooking; and the difference in the amount of sugar needed in each case would be marked.

Department of Agriculture, Washington.

H. E. Van Deman.

Periodical Literature.

The October issue of the *Bulletin of Miscellaneous Information*, issued by the authorities of the Royal Gardens at Kew, contains an article on a forest-plague in Bavaria, where the Pine forests are injured by caterpillar of a moth (*Lipparis Monacha*). It appears that these caterpillars have attacked the forests of central Europe at different times during the last 200 years. They make their appearance after long intervals, but the destruction which they cause is serious. In Bavaria alone it is estimated that the loss to the revenue from woods and forests will amount next year to \$200,000, and in some of the forests attacked by the "nonnen," as the pest is known there, the excreta from caterpillars is said to lie six inches deep. The following note from the Bavarian Forest Administration on this subject is reproduced from the Bulletin:

"The Forest Department of the Ministry of Finance state that the 'nonne' plague is now extended over nearly all Bavaria south of the Danube in scattered tracts. The infested districts are estimated at about 22,000 acres. The fertility of the insect is so great, and its numbers so enormous, that the Forest Department fear that no measures of destruction are of any avail. 'We stand powerless before the immensity of the pest.' The insect attacks chiefly the Pine and Fir, with which Bavarian forests abound, but in default of these it does not despise the Beech, Oak and other forest-trees, and is even known to feed on shrubs and garden plants. It never attacks Corn or Wheat, and, curious to say, there is one tree, the Horse-chestnut, which it will not touch.

"The means of destruction are various. Forest-bonfires of worthless wood form an easy means within reach of all communes. The insects are attracted by the fire and are smothered in the smoke, but only a comparatively small number are killed. Children and boys are also sent out to destroy the insects. From September to April the eggs can be found in the bark and destroyed, and in April the very young caterpillars can be more easily killed; all these, however, are mere partial measures. The only efficient general measure seems to be the cutting down of whole forests when much infested, in which case the remedy is almost worse than the disease. One other method is used by the state, but not within reach of communes, and therefore not described in the official pamphlet. A large electric light is placed in the forest by night. It attracts hundreds of thousands of 'nonnen' to the mouth of a large funnel through which a rapid exhaust current of air is forced, sucking the insects by thousands into a hole under the earth, where they are buried. Even this is only a partial measure, for in a forest containing perhaps a hundred millions of 'nonnen' it is not much to destroy 200,000 or 300,000.

"The Forest Department consequently fear an even greater extension of the plague next year, and an even worse danger is threatened—namely, that of the 'bark beetle,' which, burrowing under the bark, is much more injurious to the wood and more difficult to kill. It is always found that where the forests are injured by any special cause the 'bark beetle' follows and attacks the injured or diseased wood in vast numbers, and this is greatly feared will be the case in 1891. Great numbers of trees are being felled, but to avoid flooding the market with timber and causing a ruinous fall in prices, contracts and agreements have been entered into with neighboring forest-owners and the large timber-dealers by which only certain quantities will be sold at a time, and prices will be maintained. The yearly 'cut' in the other Bavarian forests has also been much reduced."

The following account of the "nonne" is translated from the Bulletin for the *Münchener Neueste Nachrichten*:

"Just as men and beasts are from time to time carried off in multitudes by epidemics, which epidemics it has not yet been found possible entirely and finally to suppress by art and science, and by doctors and veterinaries, in like manner the trees of the forest are now and then attacked and destroyed by forest-insects. Fortunately these vanish, as a rule, as quickly as they come, by the operation of natural agencies. This is the only consolation we have in view of the desolate condition to which many of the Pine forests of Germany, and in particular of Bavaria, have been reduced by the horrible devouring caterpillar, the 'nonne.'

"Before now in earlier centuries our woods have been attacked by similar calamities, and yet the German forests grow green and thrive, and yield, year by year, higher rents. This may serve to calm too anxious minds and to correct the views of those who are so ready with their judgments, and who ascribe the blame of the misfortunes which have fallen on the forests solely to the forest-officials.

"However, the present visitation has nothing particu-

lar to do with the forest-training nor the new forest-organization, nor with the style of forest-husbandry in vogue, nor with the aims of modern woodcraft, for it is well known that destruction by insect plagues occurred hundreds of years ago, and therefore at a time when the trees grew of themselves in primeval fashion, and there was no question of forest-training nor of any particular forest-husbandry. Besides this, the fact is not in dispute that the destructions caused by insects are much less intense in forests of mingled broad-leaved and needle-leaved trees; but this money-loving world unfortunately insists on quick-growing Pine forests instead of safe slow-growing woods."

The report here gives a brief account of seventeen of these insect invasions with their dates, which occurred between the middle of the fifteenth and the beginning of the present century. Of these visitations the last one, which raged in the Pine and Fir forests of Lobenstein, Schleiz, Ebersdorf and Saalburg from 1794 to 1797, worked vast destruction, so that the loss was reckoned at 2,000,000 cords of wood. "Bechstein, in his *Forest-Insectology* (1818), describes the great destruction caused by the 'nonne' caterpillar in 1794-97 in Vogtland, Lithuania and west Russia, and gives figures which correspond exactly with our present situation. Seventy-two years ago he wrote as follows:

"'It is horrible to travel in districts where these caterpillars swarm. Many thousands crawl up and down the trees. One cannot take a step without treading on a number of them. There is a perpetual rain of their excreta, which often lies six inches deep, and being dissolved by the rain, collects in puddles, which diffuse a pestilential stench. One can form no idea of the magnitude and terrible nature of the destruction. Fortunately, Nature herself stopped the pest through a kind of dysentery which attacked the caterpillars in the beginning of June, 1797. This deadly sickness was attributed to a kind of mildew. The caterpillars collected together in great thick clumps four to six inches across, the excreta became pale, the intestines dirty, and so they died, leaving behind them a disgusting stench.'

"As to the measures of prevention and suppression of that day, they hardly differed from those in use now. Bechstein, in 1818, recommended, first, protection and encouragement of insectivorous birds; second, protection of useful insects which attack and pursue the "nonnen"; third, scraping the eggs off the trees with brooms and scrapers with long and short stems; fourth, picking off the moths, caterpillars and cocoons (in 1796 the Prussian district administration at Hof caused 1,838,000 female butterflies to be caught, and paid six kreutzers for every thousand); fifth, the lighting of a number of small bonfires on dark nights (for it is well known that butterflies are attracted by the moonlight), and they paid in Bayreuth in 1796 for one night's maintenance of fire and bringing wood five groschen; sixth, isolation of the districts attacked by broad paths and ditches; seventh, cutting off in March and April of the branches nearly to the vertical and burning them; eighth, cutting down of whole standing trees, and burning of the branches and bark; ninth, removal of moss and litter from the forests and burning, if eggs or caterpillars are found therein.

"In connection with the injury caused by the 'nonnen' in this century, we may briefly mention here the extensive plague of 1839 and 1840 in upper Suabia (Württemberg), which ravaged many hundreds of 'morgens' of Pine forest. The same thing was repeated in 1855, and at the present moment is appearing almost in the same spots in a very serious manner. But the most considerable 'nonnen' pest of all took place in Russia, and spread from 1845 to 1868 in a most devastating manner over Poland, Lithuania and east Prussia. The invasion in east Prussia began suddenly in 1853, in the night of July 29th-30th, and covered a superficies of about sixty German square miles in the administration of Gumbinnen, after it had already crossed over in 1851 and 1852 the southern boundary of the administration of Königsberg. At that time the moths were driven by a storm into the sea while on their way, so that the insects were thrown by the waves upon the coasts for a distance of ten German miles in a bank seven feet wide and six inches thick, and were used as manure by the coast inhabitants. The extent of the ravages in Russia at that time was 6,400 German geographical square miles, and in east Prussia 600, making a total of 7,000 miles. At the very least, 55,000,000 Prussian cords of wood, or 185,000,000 cubic yards of wood, became the prey of 'nonnen' and bark beetles.

"The examples given suffice to show that the 'nonnen' have made their appearance in former centuries in large numbers, and have generally disappeared with equal suddenness. The present catastrophe will likewise come to an end after causing heavy losses, though it may possibly return many

years later. But we possess no radical remedy against the caterpillar, and it seems doubtful if we shall ever find one. At all events, it is the duty of the forest-managers, forest-owners, the Government and the whole population to come to close quarters in every possible way with this dangerous visitor, even although Nature herself up till now has proved the best helper, and may continue so in future."

Notes.

Spiraea prunifolia is less desirable than many other shrubs of this genus, but its autumn coloring is remarkably vivid. This year it has been conspicuous for the bright crimson of its foliage.

A writer in *Gartenflora* says that a few sprigs of Rosemary laid among woolen clothes will effectually protect them from moths. New expedients for this purpose are worth trying, now that the price of camphor has risen so greatly.

The western range of the Hemlock has been still farther extended, a tree having been lately found by Mr. J. F. Bartlett, of Brainard, Minnesota, on the right or east bank of the outlet of Pokegama Lake, that is, near the north line of Section 15, Township 55, Range 26, west, in Minnesota, and seventy-five miles north-east of the intersection of the Wisconsin line with the St. Louis River.

We have received from the Minister of Agriculture and Commerce of Italy a copy of the "Annuario Generale della Orlicoltura in Italia" for the current year, a directory of the horticultural societies of the kingdom and their members, of the botanic gardens and schools of agriculture and forestry, with some cultural memoranda relating to new plants and other information of special interest to Italian botanists, gardeners and foresters.

In connection with the interesting notes on "Grapes in Eastern Massachusetts," which appear in another column of this issue, it may be well to state that the method of cultivation practiced by Mr. Smith seems to be justified by the results attained. At the exhibition of the Massachusetts Horticultural Society last month he obtained the first prize for Grapes of the following varieties: Wilder, Barry, Prentiss, Massasoit, Lindley and Brighton.

Experiments at the Iowa Agricultural Experiment Station seem to indicate that lime, added to mixtures of London purple and Paris green, greatly lessens the injury which these poisons inflict upon the foliage of trees sprayed with them. About a bushel of lime is put in a barrel and covered with water until it is thoroughly slaked. The mixture is stirred until it is very milky, and as much is added to the arsenical preparations as can be used without clogging the sprayer.

In the valuable article on American Grapes, by Mr. T. V. Munson, which appeared in the issue of this journal for October 1st, the name *Vitis palmata* was used to designate the plant called *V. rubra* by Mr. Munson. This change was for the sake of uniformity, as the plant had been figured and described as *V. palmata* in GARDEN AND FOREST (vol. ii., p. 340). It should have been stated that the change was not authorized by Mr. Munson, and that he prefers the name *V. rubra*, which he has used in other publications.

The Chrysanthemum Show of the Philadelphia Horticultural Society, which is to be held next week, beginning on the evening of Monday, November 10th, and continuing until Friday evening, bids fair to equal the best of the Philadelphia exhibitions in former years. The entries have been numerous, and the display of new seedlings will be unusually large. Exceptional interest is manifested in the award of a special premium of fifty dollars offered by a member of the Society for the best seedling Chrysanthemum, no one being allowed to compete except the veteran growers, John Thorpe, of Pearl River, New York, and W. K. Harris, of Philadelphia.

The New York Forest Commission will hold a meeting on November 5th, at eleven A. M., at the office of Sherman W. Knevals, Esq., 32 Nassau Street, New York, for the especial purpose of discussing the establishment of an Adirondack State Park, in pursuance of the resolution passed by the Legislature of 1890. In order to avail themselves of the opinions and suggestions of all parties interested, the Commissioners invite representatives from all clubs, preserves, sanitariums and other associations now existing in the Adirondack region, to meet with them for the purpose of mutual consultation and informal discussion.

A correspondent of the *Gardeners' Chronicle* recently wrote: "I have to-day flowered a *Cattleya aurea* that has two flowers to the spike; one is distinctly *C. Dowiana*, with the purple on the sepals and the gold veins on the lip distinct to the very edge; the other flower is *C. aurea* without any purple markings on the sepals or petals, and the gold veins at the sides of the lip widening until the purple disappears. I mention this to show how absurd the naming of slight varieties of Orchids is. I have been flowering some of the best looking *C. Dowiana* I ever saw, but have not been fortunate enough to find a single Hardyana among them. From experiments I have made I am convinced that a clear light has much to do with the intensity of the coloring of these Cattleyas; and some whose petals are mottled with rose or purple when suspended close to the glass in a good light will have no red coloring on the petals if kept in a shady place."

Monsieur Lemoine, of Nancy, sends us a colored plate of another series of four of his new hybrid Gladioli. There are two of the Nanceianus hybrids: Le Grand Carnot, with very large bright, orange-scarlet flowers, with conspicuous, sulphur colored spots on two of the lower segments and shaded with purple toward the interior; Harry Veitch, with dark maroon-red flowers, the lower divisions marked with straw colored and bright red spots. Two new hybrids of the Lemoinei section complete the group. They are: Alice Wilson, with large, well-formed flowers with reflexed segments, displaying the interior, which is cream colored, slightly shaded with rose. Another of the same class is Nuée Bleue, with smaller, violet-blue flowers, marked with large, darker violet spots, separated through the middle by a yellow ray. Several more new Nanceianus hybrids are sent out this year from the Nancy nursery, including Dr. H. P. Wolcott, Kléber, Masséna, Undine, and Professor Sargent.

In an account of a conversation recently held with Colonel H. Gardner, the special agent of the Census Office for the collection of statistics with regard to viticulture, a correspondent of the New York *Sun* reports him as saying that "there are in round numbers 400,000 acres of land in this country planted to vineyards, of which 300,000 will be in bearing this year. This is an increase of 220,000 acres in vineyard area during the past ten years, and an increase of over \$10,000,000 a year in the capital invested. Of the area of bearing vines in the country, California alone has 150,000 acres, including 25,000 acres of Raisin-grapes. That state also has of the total investment of capital nearly \$78,000,000. Between 30,000,000 and 40,000,000 gallons of wine will be made in the United States this year, of which California will produce more than half. Seven-eighths of the grapes of California go to the wine press. Four-fifths of the grapes grown in all the rest of the United States are for table use. California alone grows the Raisin-grape."

Bulletin No. 12 of the United States Department of Agriculture is devoted to an account of the "Grasses of the Southwest," with plates and descriptions by Dr. George Vasey of the species peculiar to the desert region of western Texas, New Mexico, Arizona, and southern California. The region embraced in this work so far as the valleys are concerned is principally a desert. Grasses are scanty, not in variety of species, but in distribution. Some are short-lived, springing up after summer rains, maturing rapidly, and then disappearing. The perennial species grow generally in bunches, with roots which penetrate deep into the soil and thus enable them to withstand the effects of protracted drought. Grasses nowhere form a dense sod as they do in regions of more equally distributed rainfall. As Dr. Vasey points out in his introduction, the most important agricultural question before the people of this region is how to increase the production of Grasses and other forage plants. The Department of Agriculture is endeavoring to solve this problem by means of various experimental farms situated in different parts of the western and south-western parts of the country, and the sensible opinion seems to be gaining ground that if any Grasses can be profitably cultivated in this arid region it will be some of the native species, which naturally are better fitted to support the hardships of the peculiar climate than others developed under more favorable circumstances. The first step, naturally, in experiments with the native plants of a country is for the experimenter to learn something about them, and this he will be able to do by the aid of this work, which admirably accomplishes its purpose through the capital illustrations and Dr. Vasey's descriptions. Fifty plates are given in this first part, which are to be supplemented by fifty more, now in course of preparation. The plates are from drawings made chiefly by Mr. William R. Scholl.

The Axe in its Relation to Ornamental Trees.

IT is a curious fact that Americans, who have destroyed more trees wastefully and foolishly than the people of any other country, and have stood and seen their forests, the envy of the rest of the world, swept away with hardly a voice raised in protest, are more unwilling than other people to use the axe in cases where the cutting of trees is really essential. A hundred square miles of forest may be swept by fire from some mountain range through the carelessness of an idle hunter, a mountain stream may be ruined, and the fertility of a smiling valley threatened. It is all taken as a matter of course, and is looked on as one of those unfortunate occurrences which the community is powerless to prevent. The forests of the national domain are robbed of their timber, and the public is satisfied with the simple acknowledgment of the general government that it has not the power or authority to protect its own property against the organized bands of plunderers who have been preying on it for a quarter of a century or longer. This indifference to trees when they are composing elements of the forest is a marked feature in American character, and is all the more marked from its contrast with our feelings about trees individually, especially trees which we have planted ourselves or have seen planted. When a tree is cut in one of the parks of this city there is a protest raised against the so-called barbarity of the act by a hundred voices which are silent about the destruction of the Adirondack forests. The protest in the one case is as much the result of ignorance and indifference as the silence in the other; and it is as necessary to use the axe, if the beauty and value of ornamental plantations are to be maintained, as it is to save the forests on the headwaters of important streams.

Most people hate to see a tree cut on the grounds which surround their homes, on the borders of the highway, in parks or squares or other public places. This is one of the principal reasons why, out of the millions of trees which are planted or spring up naturally every year in the eastern states, so few ever reach maturity or develop their true beauty.

It is a rare thing in all the more settled parts of the country to see a well grown tree. The soil and the climate are

favorable, nevertheless, to the growth of trees; the variety which can be grown is very large, and trees have for many years been planted in great numbers in and near the towns of all the eastern states. The poverty of results obtained from the labor and money which have been expended in the embellishment of towns and of country estates by planting can, in most cases, be traced to the dread of using the axe. This is a fact which cannot be repeated too often or insisted on with too much emphasis. An Arbor Day is now devoted in nearly every state to planting trees. The custom is a good one in so much as it draws the attention of the young to trees and to their value; but the mere setting of trees in the ground is by no means all that is required in successful tree-culture, and some part of Arbor Day ceremonies might well be devoted to the care of trees already growing by supplying them with sufficient light and space for their requirements.

It is not very easy to lay down general rules for the proper thinning of trees in ornamental plantations, under which title we include all trees which do not grow in the forest. It is an operation dependent on judgment which can come only from experience; and it must depend on local conditions, such as the character of the soil occupied by the plantation, the nature of the trees which compose it, and the object which it is intended to serve. This much, however, can be said: no tree can grow into a thing of individual beauty unless it has from the beginning of its life sufficient room for growth in all directions. The branches of two trees not only should not be allowed to touch until they have reached their full size, but there should be sufficient space between them to enable the light to penetrate to the lower branches of both trees. When it is the object of the planter to produce eventually the effect of a grove or of a dense wood, it is necessary to keep the young plants sufficiently separated to permit the growth of lateral branches for many years. If this is not done, the individual trees lose vigor, become stunted and die early, and the object of the plantation is not accomplished.

It is a very common thing to find a plantation made to screen some unsightly object, like a building, a highway or the boundary of a park, fail to accomplish its object. The foliage is all at the top of the trees, the unsightly object it was intended to hide appearing between their trunks. This is the inevitable result of insufficient thinning when the plantation was young. The answer which people almost invariably make to a suggestion to thin one of these border plantations is, that if it is done the unsightly object will be brought into prominence. On the contrary, it is the neglect to thin that destroys the value of the trees for the purpose for which they were planted. It is difficult to make people comprehend that one healthy, well branched tree covered with leaves is more valuable than half a dozen small, stunted trees deprived of their lower branches and furnished with scanty foliage, or that crowding will produce this result. It is extremely difficult to make people look ahead in the matter of trees or to see in their mind's eye a tree twenty or thirty years after it is planted.

There are some varieties of trees which are more valuable than others on particular soils, and there are always in every plantation some individuals more promising than others. In thinning, those varieties and those individuals which promise the longest lives and the greatest beauty should be spared and the others destroyed. If a man is curious about trees, he will naturally preserve the specimen of a rare species and sacrifice common trees. One man may prefer to have his home surrounded by conifers, and another by trees with deciduous leaves. The successful thinning of a plantation depends on knowledge and taste. The more the man who is entrusted with planning work of this sort knows about trees, therefore, the more successfully the work will be done. Such knowledge is gained by experience, by being among trees, by thinking of them in their various aspects, by living with them and

loving them; and this is the best time of the year to consider trees with the view of improving their condition by the aid of the axe. The best time to examine them is just as the leaves have fallen and while the weather is still pleasant, and to mark for future cutting all that are doing more harm than good, and which are, therefore, better dead than alive.

But work of this sort must not be done hastily or carelessly. It is much easier to kill a tree than it is to rear one up; and the wise man does not cut a tree until he has considered the result of doing so from every point of view. It is best to hesitate in every doubtful case, and to think the matter over again before the axe is actually laid at the roots. There is, however, a great difference between the careful consideration of a matter of this sort and entire want of action; and as a general rule a man rarely makes a mistake in cutting too much or too often. If an error is made, it is in the other direction; and too little action rather than too much is the destroying element of our plantations.

A familiar phrase in the mouths of many people is, "I cannot bear to cut a tree, I love trees too well." The person who utters it does not love trees intelligently, and does not take the trouble to devote even a few minutes of serious thought to them and to their requirements. The man or woman who really loves trees soon learns enough about them to realize that there is not room enough for all that are planted or spring up, and that the kindest thing which can be done for a tree is to help it in its hard struggle for existence. The true lover of trees uses the axe freely, and the outcry against its use springs from sentimentality based on ignorance. There is no better week in the year than this to begin to learn about trees and their needs, or to determine if the axe cannot be used with advantage to the trees we encounter in our walks abroad.

A FORTNIGHT ago, among the numerous seedling Chrysanthemums raised by Mr. John Thorpe, Pearl River, New York, there was a long frame filled with plants which had been produced by crossing the varieties *Roi des Précoces* and *Gloriosum*. With half of these seedlings *Gloriosum* was used as the seed-parent while *Roi des Précoces* furnished the pollen. With the other half the process was reversed, *Gloriosum* in this case furnishing the pollen and the early variety being used as the seed-parent. The plants were not mixed indiscriminately, but the seedlings of each kind were massed together, and the striking fact which appeared was that the line between these two classes of seedlings was as distinctly marked as if they had been different species of plants. At one end of the frame the plants which had originated with *Roi des Précoces* as the mother plant had bold foliage and stiff stems with the flowers all standing face upward. In the other, the foliage was more delicate and the stems were weak and bent down under the weight of flower-buds. In both cases the influence of the male parent could be noted in the character of the flower, although the *Gloriosum* type of flower seemed to be the most prevalent.

The result exhibited here suggests the question which has been often asked whether there is any special class of qualities mainly transmitted by the male parent and another class of qualities mainly transmitted by the female parent—that is, if we desire, for example, to cross a specially hardy plant with one which is more delicate in constitution, although it possesses other qualities which we wish to transmit in the cross-bred plant, which variety shall we use for seed and which for pollen? If a hundred seedlings should be selected from a Tea Rose which had been fertilized with the pollen of a Hybrid Perpetual Rose and a hundred more with the same Hybrid Perpetual fertilized by a Tea Rose, which of the two lots would be likely to have more of the fragrance of the Tea or of its particular coloring? Which lot would be likely to excel in hardiness

and possess the constitution of the Hybrid Perpetual and its habit of growth?

This is only one of the questions which are of interest to the hybridizer. The great majority of crosses are made haphazard, and perhaps the best of them have been the result of mere chance. There are a few experts who, by long trial, have discovered certain principles, which, perhaps, they can hardly formulate, but which must guide them in their selection. There is no doubt but that Dr. Walcott or Mr. Thorpe or Mr. Harris could produce a larger percentage of valuable seedlings in crossing the Chrysanthemum than could any one with less experience; but after all, there is so little absolute knowledge of the subject that it may be doubted whether anything more than a very few of the most general laws can now be formulated. Of course, if there are any special principles we can hope at last to know how to make our crosses if we wish to produce a certain effect in foliage, or if we wish to originate a fruit with a certain flavor or form or color, and the same is true, if we wish to improve plants, in regard to hardiness of constitution and adaptability to certain soils and certain regions. Perhaps, after all, there are secrets here and in the breeding of animals which Nature will never reveal. However that may be, here is one field in which careful experiment with recorded results seems to have been sadly neglected.

Evergreens in the New Jersey Pine Region.

THE evergreens of the Pines are so abundant in certain localities that the foliage of the deciduous trees is scarcely missed in winter. Extensive swamps of White Cedar (*Chamaecyparis thyoides*) form broad, irregular belts of unbroken green, bordered with many low-growing, broad-leaved evergreens. Here, protected by the Cedars, we find that all the younger trees of *Magnolia glauca* hold their leaves until spring. In the south it is entirely evergreen, while here it is only partly so.

The broad-leaved Laurel (*Kalmia latifolia*) is here quite tree-like, often from fifteen to twenty feet in height, with lower bushes growing among and all around them. These thrifty younger clumps are very beautiful. Some of these shrubs have much broader and more glossy leaves than others, and the color of the young branches is a marked feature. Some have twigs of a bright yellow, others take on various shades of red, which, contrasting with the dark, shining foliage, is very effective. The narrow-leaved Laurel (*K. angustifolia*) is also here in abundance.

The Hollies attain their greatest perfection in the moist soil near these great Cedar-belts, especially near the coast, where the trees are from six to seven feet in circumference, and fairly ablaze with their scarlet berries, while beneath them their relative, the Inkberry, with shining black fruit, grows in profusion.

The little shrub, *Cassandra calyculata*, is here, with its flower-buds strung all along the terminal branches in the axils of the small evergreen leaves, ready to open on the first warm days in winter.

One of the most charming of all these smaller shrubs is the Sand Myrtle (*Leiophyllum buxifolium*), which in these moist places attains the height of three feet, while in the more open dry barrens it scarcely reaches a foot in height. This pretty little evergreen has an abundance of small shining leaves, and in May its top is covered with flat clusters of small white flowers, with ten exserted stamens with purplish pink anthers.

The Bayberry retains its fragrant leaves here until late spring, the old leaves mingling with the new as if loath to give up their hold. And the evergreen Smilax is climbing over the deciduous shrubs, clothing them with its broad, thick leaves.

The Arbor Vitæ (*Thuja occidentalis*), the White Cedar of the north, is mingling with the trees and shrubs along this moist belt, but more as a shrub than a tree of any dimensions.

Turning our attention to the ground, we find charming evergreen herbaceous plants in these moist places. One of the most lovely is our Pine-barren Pyxie (*Pyxidanthera barbata*), a little prostrate plant, growing in thick mats with small green and purplish leaves, and in early spring covered with a profusion of pink buds and white flowers.

The Xerophyllum attains its greatest perfection in these damp barrens, where it is a stately, fine plant. It consists of a thick mat of narrow, grass-like, reclining leaves, from a foot to eighteen inches in length. These clumps are quite ornamental in winter, and they are decidedly so in May, when they send up a flower-stem three or four feet in height, surmounted by a dense head of showy white flowers. Sometimes several stems arise from one clump. Its cultivation is considered difficult. Four years ago I had fifteen plants moved to my garden, where they are now all in a thriving condition. A shallow trench was made only a little lower than the surrounding ground in which they were planted. But they had been carefully removed with a large deep sod of earth surrounding each clump, and all the little shrubby plants that were growing around them were left in the sod. They are well worth all the trouble and cost of transplanting.

Farther back in the swamp, hid away among the Cedars, is the rare, local *Helonias bullata*, growing in clumps, with broad, thick evergreen leaves from six to ten inches in length. It grows almost wholly in water, and yet it is quite easy of cultivation in any common garden soil, where it will bloom in early April.

The Pitcher-plant is here in abundance, and is handsome all winter. The edge of the swamp is bordered with a thick carpet of aromatic Wintergreen in such profusion that the berries are collected for market, mostly by foreigners, who find a ready sale for the fruit in Philadelphia and New York.

I have tarried so long amongst the evergreens in the swamp that I have left no space to tell of the evergreens in the drier and more open woodlands.

Vineland, N. J.

Mary Treat.

Enemies of the Grapevine.

AT the Conference on Grapes held by the Royal Horticultural Society in September in their gardens at Chiswick, one of the papers read by Mr. R. D. Blackmore treated on the above subject, and it may be of interest to reproduce a few of his remarks here.

The enemies of the Vine may be broadly divided into two groups—namely, those of the vegetable order, chiefly fungoid, and those of the animal, chiefly insects, while a third group that cannot be referred to either of the above may be called miscellaneous.

Fungoid diseases are numerous and difficult to define even by skilled mycologists. Gardeners, however, designate them, according to their choice of aggression, as mildew of the roots, mildew of the shoots and foliage, or of the bunch or berry. Mildew on the roots is not a very extensive malady, and appears to exist only in places where the roots have missed their proper share of moisture. Mildew on the foliage or berry, however, is always a nuisance, and unless dealt with immediately is likely to prove an extensive disorder. In the majority of cases the evil is caused by a want of genial warmth. Perhaps there has been a creeping draught or a sudden fall in the temperature, or something in the air that sends a shiver through the leaves, and then in the early morning the first symptoms of mildew are seen. It may be but a little gray breath on the under side of a young leaf, or a dull curl at the tip of the shoot, but to the eye of the experienced gardener it means the vanguard of an army of pestilence. The innumerable spores of the disease fasten onto a weak spot, and suck and grow and propagate with rapidity. These conditions must be met at once. Raise the temperature, stop every crevice of draught, and if there be no young grapes to forbid it, fill the air with a moist exhalation of sulphur and quicklime painted on the pipes. The leaves, also, when infested should be treated to a dose of sulphur, and the border where the Vine is growing syringed with a weak solution of soft soap and sulphur. But if the sensitive berries are set these strong measures must be modified and the treatment prolonged in a milder form. Mildew on the foliage is bad enough, but on the berries it is far worse, being so much less accessible. A course which has even lately been recommended, of sulphuring the bunch and then dipping it when ripe in a bucket of clean water, is a poor practice and spoils the appearance of the grapes. The proper course is to remove every diseased berry, or even the whole bunch if it can be spared, and burn it. Then soak the soil with water almost hot, close every ventilator, fill the house with warmth, and syringe the floor (if it is feared to paint the pipes) with soft soap and sulphur mixed.

Young gardeners do not seem to know or realize the danger of giving "bottom air" too soon. In the main these sudden attacks of mildew arise from chill caused by ungenial currents of air, which check rapid growth and prepare the surface

for the reception of the hovering enemy. Every grape-grower has his particular crotchet, or, as he would rather have it called, his own enlightened theory, as to culture, for it is well known that grapes are well grown under different and sometimes diametrically opposite systems. Nevertheless, a time comes when principles reassert themselves. At the present day it is almost impossible to ripen a crop of grapes out-of-doors in England, yet it used to be done forty years ago. There has been no failing in the average temperature during these years, according to meteorological reports, but the failure is due almost entirely to the fact that open-air Vines are attacked by mildew, and this has discouraged growers.

Another violent and virulent disease of a fungoid nature is known as Anthracnose or Melanitis. Mr. Berkeley, the great mycologist, believed it to be identical with the "black spot" of Australia and the "black rot" or "grape rot" of America. The symptoms vary; in some cases no blackness is apparent until the last stage of the disease. The tip of the shoot is first attacked, and the unexpanded leaves assume a dirty wash-leather color. Lower down the shoot the expanded leaves become cupped and concave underneath. The entire shoot becomes dull and loses its crispness, and, if pinched, indents without breaking. The disease at last, after descending the stem, enters the older wood and quickly destroys the vine if not checked at the outset. Those kinds with thick, tomentose leaves, such as Gros Colman, Gros Maroc and Black Alicante, are the kinds chiefly attacked by this peculiar disease, while Black Hamburg, Chasselas Musqué and others appear to be exempt from it.

The usual post-mortem remedy is to "search the roots"; but these, together with the side shoots and lower leaves, are always healthy until the disease reaches them. To thwart the disease Mr. Blackmore tried sulphur in every form, quassia, tobacco water, etc., but one day, seeing by chance a can of strong liquid manure, he plunged a shoot into it; this treatment caused a speedy arrest of the evil, and, after two or three more dippings, a renewal of sound growth.

Among the insect pests which attack the roots or stems of the Vine comes first and most fatal of all, the Phylloxera; happily, however (owing, perhaps, to climate), English gardeners do not make its acquaintance. Then the larvæ of the cockchafer, Cetonia and other beetles, weevils, wireworms, etc. The grub of the cockchafer, though destructive, does little harm now, because it is not in sufficient numbers. The Cetonia is rare and does little injury. But the weevil (*Curculio vitis*), both male and female, is a great pest. It tears the leaves, nips off the young shoots, and in the case of pot-vines, honeycombs the soil, filling the cells with fat, curled larvæ, which in a young state are bluish white, passing into yellow when fully grown, and assuming a dirty red color in the pupa state. The presence of this insect in a pot is revealed by the leaves turning yellow, the young bunches of grapes flag, and unless strong measures are soon applied the plant eventually dies. Prevention is the proper remedy. The soil should be searched for the weevils, but it is often difficult to find them, as they resemble it in color. A good method of catching them is by ordinary Maidenhair Ferns, which act as traps. The weevils like them and get into the crowns to rest, and if a plant is turned upside down and shaken over a piece of white paper every morning the weevils will drop out should any be present. Decayed potatoes, apples, carrots and the like may also be used as traps for these depredators with advantage.

The enemies which attack the shoots and foliage are red spider (*Tetranychus telarius*) and thrips (*Thrips minutissima*). The latter is rarer than the former, and its presence is often due to the introduction of such plants as Azaleas, Abutilons, etc., into the vinery. When once established it is difficult to get rid of, and its ravages must be combatted by much sponging with soft soap and tobacco. The mealy-bug (*Dactylopius adonidum*) if once established becomes a frightful pest. It is often imported in spring by ants, and unless seen to then the gardener will have to cope with a mass of woolly filth later on. The vine scale is another enemy, but a brush filled with strong insecticide will soon dispatch it.

Among miscellaneous enemies of the Vine are scorching, sunstroke, spot upon the berries, cracking, rust, and worst of all, "shanking." The latter, especially, which some consider to be due to a local disease of the foot-stalk and others to the lack of nourishment, seems at present to be a malady little understood.

It may be mentioned that Mr. Blackmore is the author of the popular novel, "Lorna Doone," and his lecture, of which the above is a mere outline, will appear in full in the Journal of the Royal Horticultural Society and will amply repay the reading.

London.

Phono.

The Black Peach Aphid.

FOR many years Peach-trees in New Jersey, especially those in the sandy districts, have been in an unhealthy, thriftless condition. "They are badly dwarfed, and make only a feeble, sickly growth. The leaves are light green or yellowish, more or less rolled at the margins, and red or purple spotted from the attacks of Fungi." The trouble is not caused by the yellows, nor does it seem to be due to a particular fungoid disease. Fertilizers have been used to stimulate the trees, and kainit of potash has gradually come to be looked upon as a specific. This substance is undoubtedly a valuable stimulant and fertilizer, but it has another quality, to which, in the light of recent developments, most of its success is probably due. It is an insecticide of no mean value, and to this quality it owes the specific effect in a majority of cases. Dr. E. F. Smith, who has for many years studied the diseases of the Peach, has found that a plant-louse attacks the roots of the trees, and so devitalizes them as to check growth and give the well known yellow appearance.

This aphid (*Aphis Persicae niger*, E. F. Smith) was very abundant in New Jersey during the season of 1890, not only on the roots, but on the leaves. During the month of May, at Vineland, the young shoots of several Peach-trees were attacked so that they were curled and dwarfed and all but destroyed. There was a similar experience in other

Fig. 70.—PEACH APHID (*Aphis Persicae niger*); WINGED VIVIPAROUS FEMALE.

localities. The forms of this insect seen on the leaves and branches are principally wingless, viviparous females, deep black and shining, smooth, with a well marked margin or series of lateral depressions on the abdomen. The young are paler, more brown in color, and sometimes with a green shade in newly born individuals. Among these are found a few winged forms, of which the annexed figure gives a fair idea.

They are of the same shining black color as are the wingless forms, but the body is not so stout and the antennae are longer. It is by these winged forms that the species is distributed. They fly to neighboring orchards, especially favoring young or nursery trees, and plant colonies which rapidly increase; and about midsummer make their way into the ground. At this time the leaves are comparatively deserted, but the roots are swarming with wingless forms. Nursery-trees now begin to sicken, and many die off. Dr. Smith mentions several cases of thousands of trees entirely killed, while one instance at least has come under my own notice in which the seedlings were rapidly succumbing to the attacks of this insect. Other failures reported to me are almost certainly referable to the same cause. On the root system the development continues, only wingless forms being produced, and this goes on until winter. In the mild winter of 1889-90 they continued nearly through the season. In the spring they come to the surface, and the life cycle begins afresh. There seems no place in this existence for the egg state, and true, sexed individuals are not known. There seems to be a continuous, agamic reproduction.

In general appearance this Peach-louse is very like the species infesting the Cherry (*Myzus cerasi*, Fabr.); but there are

some curious differences. The antennae in many of the plant-lice are furnished with sensory organs, the exact use of which is still unknown. In this species these sensory pits are most remarkably developed; not only are they very numerous, but they are on every joint, and are also very large. The figure brings out the structure fairly well.

Fig. 71.—ANTENNAL JOINTS OF PEACH APHID.

a, antenna of young louse; b, first long joint of winged form; c, second long joint; d, third long joint; e, whip joint; f, sensory pit from top; g, same from side.

In the Cherry-louse these sensory pits, though still of good size, are very much reduced in number, and they are entirely wanting on the second long joint. On the third joint there is but a single pit near the tip, and only on the whip joint are the two species at all alike. Another curious fact in these antennae is, that the joints are imbricated, or with scale-like markings, as rather roughly indicated in the figures. The injury is done by sucking the sap of the tree and thus diverting the nourishment.

While the insects are above ground they are quite readily dealt with. The ordinary whale-oil soap—Leggett's Anchor Brand—is as good a remedy as any; it should be used at the rate of one pound in six gallons of water; this will kill the lice without injury to the foliage.

This insect in its underground state is the most destructive and the most difficult to deal with, as it cannot be treated with insecticides. The kerosene oil emulsion might reach it, but it would have to be very thoroughly applied. We have a much better remedy in the potash salts, and of these the kainit is best, perhaps because it contains more salt than the muriate. This has the advantage of being stimulant as well as insecticide, and the entire cost of the application is retained in the vigor of the tree. The insecticide is therefore "thrown in," for only the fertilizer is paid for. The salts should be scattered broadcast, in good fertilizing quantity, and preferably before a rain, so that the salt water may reach the roots in the quickest possible time. Never hill up the trees with potash. The chances are that by doing so you will kill the trees as well as the insects.

Fig. 72.—ANTENNAL JOINTS OF CHERRY APHID. (*Myzus cerasi*, Fabr.)

a, first long joint; b, third long joint; c, whip joint; all of the winged viviparous female.

Plant Notes.

Some Recent Portraits.

HÆMANTHUS LINDENI, a beautiful new plant discovered by Mr. Auguste Linden somewhere in the Congo region, which has recently flowered for the first time in cultivation in the nurseries of L'Horticulture Internationale, Brussels, is figured in the issue of *The Gardeners' Chronicle* of October 18th. Mr. N. E. Brown, who describes it, finds that the plant remains a considerable time in flower, the head being very large, and producing a hundred or more large and brilliantly colored flowers, which open in succession. He kept the specimen which Mr. Linden sent him in water for nearly two weeks, during which time the flowers continued to expand. "This species does not form a true bulb, but has a thick, solid root-stock, from which arise six or eight leaves in two ranks that persist for a long time, the plant being practically evergreen." The scape arises from the side of the leaves, is moderately stout and about eighteen inches high. The umbel of flowers is six or eight inches in diameter, with a hundred or more flowers opening in succession. The individual flowers are two inches in diameter, with a tube nearly an inch long, and long, slender lobes, which are bright salmon-scarlet color, fading to pink. The long filaments are nearly of the same color as the perianth, although whitish at the base and furnished with purple anthers. Specifically, Mr. Brown points out, this species is most nearly allied to *H. Angolensis*, but the flowers are much larger and the leaves are dissimilar.

PÆONIA MOUTAN.—There is in *The Garden* of London, published on the 18th of October, a beautifully colored plate of a single white Tree Pæony, a seedling raised by Messrs. Kelway & Sons, of Langport, who have been experimenting during the last twenty years in raising seedlings of these plants. The seed ripens in September and is sown as soon as gathered in frames without artificial heat. Some of the seed vegetate the following year, and the seedlings are allowed to remain in the seed-bed for two years. The Langport system is to plant the seedlings in the month of October, in well enriched soil, in drills two feet apart and six inches between each plant in the drills. Here they remain for two years more, and are then finally planted three feet apart each way to bloom. The best seedlings are selected for stock and propagated after grafting in the following manner: "First procure a sufficient quantity of tubers of *P. Sinensis*; cut these into lengths of about six inches; then take grafts from the sorts you wish to increase and insert these into the upper end of the tuber in the ordinary way of cleft-grafting, tie securely and cover the junction with grafting wax so as to exclude the air. These should now be potted into five-inch pots, using a good rich compost; the pots should be plunged into frames unheated; give a good watering, and cover the frames with a thin mat to partially exclude light. In the winter they should have an extra mat to protect them from severe frost. The best time to perform this operation is in the months of August and September." To show the value of these plants as ornaments for the garden it is only necessary to refer to a specimen which a correspondent of *The Garden* describes as eight feet high and twelve yards in circumference. This wonderful plant had never failed during a quarter of a century to produce annually several hundred blooms. Tree Pæonies, which start to grow early in the spring, and are, therefore, liable to suffer wherever late spring frosts occur, really do much better in this country than they do in England, and it is surprising that their value is not more generally appreciated and that they are not more frequently planted. The single-flowered varieties especially are rarely seen, although they are more beautiful and desirable than those with double flowers. There are probably still many very fine varieties to be found in Japanese gardens which have not yet reached this country or Europe.

A FRUITING GINKGO.—The Japanese Ginkgo-tree has probably rarely fruited in this country. The tree is not fruitful until it attains a considerable age, and, as the sexes are separated on different individuals, it is essential that male and female trees should grow together in order to secure fertilization; and as it is impossible to distinguish the sexes until the trees flower, the securing of both in the same plantation is a matter of mere chance. A tree planted in the grounds of the Military Academy of Kentucky produced fruit several years ago, and one of the trees in Central Park in this city is now fruitful. Miss Graceanna Lewis, of Media, Pennsylvania, sends us an admirable drawing of the Ginkgo-fruit produced by a tree in the garden of Charles J. Wistar, Esq., at Germantown, Pennsylvania, now about forty years old. This tree bore a

few fruits last year for the first time. The fruit of the Ginkgo, which few people who are not botanists realize is a conifer, is drupe-like, with a large, hard nut surrounded by thick oily flesh which soon becomes rancid and is very disagreeable. The kernel of the nut, however, has a delicate almond-like flavor much liked by the Japanese, who use great quantities of these seeds as dessert fruit.

Foreign Correspondence.

London Letter.

AUTUMN COLORS.—The weather here for the last six weeks has been remarkable for the absence of rain and an unusual amount of sunshine. The effect is seen in the bedding-plants and others placed out-of-doors for summer effect, which are now at least as good as they have been at any time during the year. Planting is delayed because of the dryness of the ground; indeed, the leaves of deciduous trees and shrubs are only now assuming their autumn colors. The conditions above named, coupled with a few slight frosts, have been favorable to the development of color in the leaves of most trees and shrubs. The Oaks, Beeches, Chestnuts, Maples, Liquidambars and Poplars among trees, and the Spiræas, Sumachs, Azaleas, Vines, etc., among shrubs, are especially rich in the glow of their golden, crimson, chocolate and scarlet hues. The Tupelos, *Nyssa multiflora* and *N. sylvatica*, are like flaming fires in color. Amongst the Sumachs the most noteworthy, on account of its beauty as much as its rarity, is *R. cotinoides*, for which Kew is indebted to Harvard. It forms a compact mass two yards through, and its leaves are now wholly rich orange in color. Apparently this species is quite at home in an ordinary border at Kew. We have not yet learned to make as much use in gardens of these autumn glowing leaves as we might. One frequently notices beautiful effects, which are the results of accident rather than design, in plantations and even in forests. These if reproduced in the garden would be delightful. We want some one to set down for us the names of the plants to use for autumn effects, such as those described, and the positions they thrive best in. Mr. Jack and other correspondents did something toward this last year in GARDEN AND FOREST. The brilliancy of color in many of these leaves in autumn is quite equal in effect to anything produced by flowers, and in a favorable season the leaves remain in beauty at least as long as flowers. And yet I think I am right in saying that in most gardens the usefulness of autumn-tinted trees and shrubs for producing a picturesque effect is either unknown or ignored. The Azalea-garden at Kew now is as charming in the varied hues of the leaves as it was when the flowers were the attraction. This is equally true of the shrubby Spiræas and of many other *Rosaceæ*. The Sumachs are almost singular in owing their favor in most gardens to the brilliant colors assumed by the leaves in autumn.

The Sea Buckthorn (*Hypophae rhamnoides*) by the side of the lake at Kew is as heavily laden with bright orange berries as the best fruited *Pyracantha* I ever saw. Is it known as a fine shrub in your gardens? Of course a male plant must be planted near the females to get fruits.

ORCHIDS.—*Cattleya Bowringiana* is a very useful plant, as it flowers late in the autumn when there are comparatively few Orchids in bloom. Its colors are warm and attractive, the flowers are elegant, and they last well. It may be called an autumn-flowering *C. Skinneri*. Another species of *Cattleya* which is flowering now is *C. maxima*. There are varieties of this so poor as to be scarcely worth growing; but in the variety named *Peruviensis* we have a first-rate plant, very free in the production of flowers, whilst the colors are brighter and the size almost twice as large as in the ordinary forms.

C. du Buyssoniana is a new species, of which plants in flower were recently exhibited in London by M. Linden's Company, of Brussels. It may be called a variety of *C. amethystoglossa*, with sepals and petals cream-yellow and a rich mauve labellum. The same company exhibited a plant in flower of a magnificent variety of *C. aurea* named *Lindenii*. The sepals and petals were of a clear lemon-yellow color, not buff, as is usual in this *Cattleya*, whilst the lip was enormous in size and heavily penciled with golden yellow. A series of varieties of this newly introduced *Cattleya* were exhibited under the name of *C. Warocqueana*, but which has been described by Mr. Rolfe as a variety of *C. labiata*. It appears to be about midway between the sub-species *C. Trianae* and *C. gigas*, and is really distinct, large flowered, handsome and apparently easily cultivated. Some of the flowers exhibited measured seven inches across, the sepals and petals were of good substance and two and a half

inches across, whilst the lip was funnel-shaped, nearly four inches long, with a wide spreading undulated limb. The colors ranged in the different varieties from rich rosy mauve to pure white, the labellum being more or less deep maroon and yellow. Their varietal names were *Regalis*, *Amethystina*, *Delicata* and *Flammea*. There are many beautiful forms of *C. aurea*, but the rarest and most delightful of all is that named *Imshottiana*, of which Baron Schroeder exhibited a plant in flower last week. It has milk-white sepals and petals and a labellum colored as in the type. A specimen of *Cypripedium Fairreanum*, bearing seven elegant flowers, was shown from the Baron's collection, the richness of which is often

little account as a garden Orchid; *Lælia Arnoldiana*, very similar to, if not the same as *L. Crawshayana*, and *Catasetum Bungeothii*, var. *Randii*, remarkable in having cream-yellow flowers instead of white, as in the type. These were the most striking of the Orchids exhibited at the last meeting of the Royal Horticultural Society.

Ærides Lawrencei is the largest flowered, and, at the same time, one of the most beautiful species known. It has lately become plentiful owing to a large importation of it by Mr. Sander, and its flowers are not now uncommon in collections. But in 1883, when first introduced, a single example was purchased by Sir Trevor Lawrence for 235 guineas. A plant of it

Fig. 73.—*Celastrus articulata*.—See page 551.

abundantly manifested at the meetings of the Royal Horticultural Society, in which the Baron takes such an active interest. Besides the above he also sent several plants in flower of his magnificent variety of *Dendrobium Phalanopsis*. Some of the flower-scapes were twenty-one inches long, and bore each six or seven flowers, which were three and a half inches across, and colored a rich rosy mauve, almost crimson, the color of the curiously formed labellum being a deep velvety maroon. Although introduced ten years ago from north Australia, yet this species is extremely rare in cultivation. I am informed, however, that the Linden Company, at Brussels, have lately imported about 2,000 strong plants of it. *Lælia grandis vera*, a fine form, with broad nankeen-colored sepals and petals and a rose-purple labellum blotched with maroon; *Aganisia cœrulea*, a rare plant of some interest on account of its peculiarly formed and uncommon colored flowers, otherwise of

now flowering at Kew was obtained several years ago for *A. Sanderianum*. It is related to *A. odoratum*, indeed probably only a variety of it, but the flowers are one and a half inches across and fully as long, and they are white, with magenta tips to the segments. *A. Sanderianum* is almost as large, but it differs in the form and color of the labellum. We are as yet ignorant of the habitat of these two noble *Ærides*, but it is probable that they occur together.

Pleiones are the gayest Orchids in flower now at Kew. Some of the pans in which they are grown are only ten inches across, yet I counted seventy-five flowers on one panful a few days ago. When understood, Pleiones are very easily cultivated. They require a rich soil, chiefly turfy loam and leaf-mould, no water after potting until they have pushed their new roots well into the soil, and then plenty until they lose their leaves again. A position near the glass in a sunny, airy greenhouse suits all

of them except *P. præcox*, which thrives best when grown in a warm house. When the flowers are opening the soil should be at once saturated and afterward kept just moist. Many people err with these plants by trying to grow them in a high temperature and by failing to give them a rest in a dry, sunny house from the time when the leaves fade until the flowers open.

Renanthera coccinea, the Chinese Air-plant, is one of the most gorgeous Orchids, but it requires a considerable amount of head room to persuade it to flower. In tropical countries it is a favorite plant for verandas or to grow in masses in sunny positions. The stems grow almost as long as the Vanilla, and the stronger and longer the stems the larger the inflorescence will be. About six years ago a few newly imported small pieces of this *Renanthera* were fastened to a dead Fern-trunk, which was placed in a sunny position in the Palm-house at Kew. One of these pieces is now nine feet long, and it bears a raceme of about sixty large, rich orange-crimson flowers. Compared with what is produced by well cared for plants in the tropics this is small, still the flowering of this plant in glass houses is of rare occurrence. By training the stems horizontally it is possible that they may be induced to flower even in small houses. The plant revels in sunshine and moisture.

New or Little Known Plants.

Celastrus articulata.

ALTHOUGH discovered by Thunberg and first published more than a century ago, no figure, it seems, has appeared before of this handsome Asiatic species, which possesses very considerable value as a garden plant.

Celastrus articulata,* in cultivation, is a stout, rapid-growing and very vigorous, leafy plant, with twining stems, growing to a height of ten or fifteen feet. The bark is light brown or ashy gray, and is conspicuously marked with numerous small, pale, wart-like excrescences. The leaf is obovate, orbicular or oval, coarsely crenulate-serrate, contracted at the apex into a short, broad point, and at the base into a long, broad petiole. It is membranaceous, with a prominent midrib and primary veins and rather conspicuous reticulated veinlets, and is often, when fully grown, four or five inches long and two and a half to three inches broad. It is dark yellow-green on the upper, and paler on the lower surface. The small yellow-green flowers are produced in short axillary three-flowered clusters less than half the length of the petioles, and appear when the leaves are rather more than half grown. The fruit is globose or sometimes obovate, and pale green when it first ripens. Later and after opening, the pod turns bright, clear yellow, making a handsome contrast with the brilliant orange-colored aril of the seed. It is produced in great profusion often on short, spur-like, lateral branches, and does not disappear until late in the autumn or until long after the falling of the leaves, which, as long as they remain on the plants, nearly hide it from view.

Celastrus articulata is apparently widely distributed through northern and central China and through the northern parts of Japan. It shows, however, considerable variation in the form of the leaves, specimens collected by Dr. Henry (Nos. 5640 and 5986) in western China, and referred to this species by Professor Oliver, having ovate-acuminate leaves, slightly and remotely serrate only.

Celastrus articulata has been cultivated for several years in the Arnold Arboretum, where it was first sent by Mr. S. B. Parsons, of Flushing, New York, in 1879. It has also been raised here from seed collected by Dr. Bretschneider in the neighborhood of Pekin. It is perfectly hardy, and grows with the greatest rapidity and vigor, and has been found useful in covering rocks, walls and waste places; and late in the year, after the leaves have fallen, it is exceedingly ornamental.

**Celastrus articulata*, Thunberg, "Fl. Jap.," 97.—Bunge, "Enum. Pl. Chin. Bor.," 97.—Maximowicz, "Mél. Biol.," xi., 202.—Franchet, "Pl. David.," 70.—Forbes & Hemsley, *Jour. Linn. Soc.*, xxiii., 122.

Articulata, the specific name in the "Flora," is, as Maximowicz has pointed out, a misprint for *orbiculata*, the name used by Thunberg in his preliminary catalogue of Japanese plants *l. c.* xlii.

Although much more vigorous, and a larger and more rapidly growing plant, it is less beautiful than the North American species, *Celastrus scandens*, the Climbing Bitter-Sweet or Roxbury Waxwork, in which the flowers are not axillary, but are produced in long, raceme-like clusters, terminating the branches, so that the fruit is raised above the leaves, and is a conspicuous and handsome object all through the early autumn, when that of the Asiatic species is hardly noticeable. The fruit of the American species is moreover rather larger and more brilliantly colored.

The figure on page 550 is from a drawing made by Mr. Faxon from one of the plants growing in the Arboretum.

Late Irish Potatoes in the South.

THE late fall crop of Irish potatoes in the south is annually becoming a more important matter as its proper treatment is better understood and the conditions for success are known.

Formerly, this late crop of Irish potatoes was the most uncertain of all, now it is as certain as any. Just at this date (October 25th), when northern Irish potatoes are retailing in Raleigh for sixty cents per peck, the outcome of the late planting is specially important. Experience has demonstrated that in this latitude the best time to plant this crop is about August 15th. In late autumns they may mature planted later, but this is about the most certain period. The practice of our best growers is to bed the small potatoes from the early crop as soon as dug in a single layer, so they do not just touch each other, cover with an inch or so of soil, and leave them until planting time. By mid-August all the immature tubers will either have rotted or dried up and the good ones will have begun to sprout. These are then planted in well prepared land, and only covered with about one inch of soil, which is rolled compactly. This shallow covering is one of the most important points, as it is found that if covered deeply they will not grow so rapidly. The crop planted August 15th will be matured by October 31st or a little later. Last fall (1889) was unusually late, and potatoes planted the second week in September made a good crop, the tops not being killed by frost until November 28th; but in an ordinary autumn it is desirable to be ready for killing frost early in November.

This late crop in this latitude can be left where they grow and covered with straw to prevent freezing. They can then be dug at any time in winter and will sell as new potatoes at a good round price. One grower in this state sold his entire crop last winter at the same price as new Bermudas, and made a very good thing of it. But the great advantage of this late-fall crop of potatoes is that they keep unsprouted all winter and late into spring, and will easily take the place of northern-grown old potatoes in spring when their quality is better known. The ease and certainty with which this crop is now grown will be a great inducement to southern farmers to extend the cultivation of late potatoes.

Raleigh, N. C.

W. F. Massey.

The Rot Among Late Potatoes.

MANY specimens of rotting Irish potatoes have been received at the Agricultural Experiment Station within a week. A large number of the Potato-growers of Salem and Cumberland Counties, of this state, will lose their entire crop. In a recent visit to the regions most affected I have seen many fields that would have yielded 100 bushels per acre abandoned as not worth the cost of harvesting. The rot has been unusually serious in southern New Jersey. One cause, unmistakably, has been the protracted rains. The *Phytophthora infestans* thrives in moist weather; and while it appears more or less every season, it is only found in low places in dry seasons, although abundant enough to furnish a constant supply of spores for future outbreaks when weather favorable to it occurs. The Fungus first attacks the leaves and afterward works its way down the juicy stems into the tubers. Mildew may reach the potatoes by the spores on fallen leaves being washed into the soil by rains. This Fungus grows with surprising rapidity. A decayed potato, brought from near Bridgeton, was cut into halves this morning at eight o'clock, and each piece placed under a bell-jar standing upon a plate holding water to produce a moist chamber. At twelve o'clock spots of white mould were visible upon the cut surface, and, when subjected to microscopic

examination, were found to consist of numerous filaments of the Rot-fungus, many of which were bearing a half dozen spores, some apparently of full size. In four hours, therefore, the filaments within the potato had grown from the cut surface and "fruited," as the term is used by mycologists. This experiment indicates how rapidly the Rot-fungus may spread in a Potato-field.

It is a well known fact that the Potato-rot Fungus, as a rule, does not do its greatest damage until midsummer, and often not until late in September, as in the present instance. It is an advantage, therefore, all other things being considered, to plant early and to have the crops harvested before the decay becomes serious. Some of the people in southern New Jersey planted late to escape the Potato-beetles. There may be other advantages, in a good year, in having the crop late, as the labor is better distributed and the yield is larger; but in a wet season it is fatal. Aside from early planting, something can be done to check the Rot-fungus by spraying the vines. Experiments have proved that compounds of copper, as the Bordeaux mixture and others, are effective for Potato-rot. The fungicide may be mixed with water containing London-purple used for the beetles, and applied at the same time. A few sprayings in an ordinary year may save the foliage.

Rutgers College.

Byron D. Halsted.

Late-Flowering Asters.

A. SHORTII.—This desirable plant is from four to five feet high, and it bears in great profusion flowers about an inch across, with pale lilac-blue ray-florets. The blooming season extends from the middle of October till the middle of November. It is found from Ohio to Georgia, westward to Illinois and Kentucky. Holding its flowers undamaged later than any other native Aster, the scarcity of other flowers and the forlorn nature of its surroundings render its aspect and utility more striking than would be the case earlier in the season. Rich garden soil, a position sheltered from strong winds and partially shaded from noonday sun are the conditions most favorable to the development of its best qualities. In an exposed sunny position or in light soil the growth of the plant is less vigorous, and, while it blooms earlier under such circumstances, the fewer flowers of indifferent quality pass away before those on plants in the right situation begin to unfold.

A. TARTARICUS.—This species comes from Tartary, having been introduced in 1818. In general appearance it differs widely from the ordinary species of this country. The thick, somewhat succulent stem is boldly erect, its surface prominently furrowed, and is generally more than six feet high. This plant has three distinct series of leaves. They are all oblanceolate and of a rather pale green color. Those of the radical series are fully two feet in length, crenate and converging at the base to a long petiole. The much smaller leaves of the stem are sessile and conspicuously serrate, and those of the branches still smaller, sessile and minutely serrate. The racemose-paniculate heads are few-flowered, the flowers, however, being an inch in diameter, with showy rays of deep reddish lilac. The plant is valuable chiefly on account of its late-flowering character, the flowers developing during the latter part of October and early in November. Half of the flowers still remain unopened. This plant is found useful here for cutting from, but in the warmer climate of states farther south it should prove still more valuable. A rather poor soil and a situation well exposed to sunshine are required to induce the plant to flower in this locality before severe frost renders it impossible.

A. TURBINELLUS.—This is without doubt the best of the late-flowering kinds. It is native in Illinois, Missouri and Louisiana. The stems attain a height of from three to four feet, and push branches from the axil of almost every leaf. The leaves are comparatively small, dark green, lanceolate and sessile. The flowers are about one and a half inches across, with ray florets of a showy blue tint, reflexed at the tip. The instances of more than one flower developing upon the same branchlet are exceptional, though one may occasionally find as many as three. The free-branching habit of the plant, however, ensures a bountiful supply of flowers. Strong clumps make an excellent display in the herbaceous border during the early part of October. The stems, of course, require staking, but if all the branches are left to assume their naturally pendulous habit the gracefulness of the mass will be materially enhanced. The time at which this Aster blooms renders it most useful for cutting, and space should be found for a few clumps of it for that reason. It is found at its best in a sheltered, sunny position in moderately rich soil. I am told that *A. laevis* is sometimes substituted for this species by

dealers. *A. laevis* is a worthy enough subject in its place; but it is a less elegant plant with much coarser leaves, and its smaller blue flowers are past when those of *A. turbinellus* commence to expand. Purchasers, therefore, should be careful as to the reliability of the dealer with whom their orders are placed.

Cambridge Botanical Gardens.

M. Barker.

Brunfelsias.

BRUNFELSIA (*Franciscea*) are handsome Brazilian shrubs, several species of which have long been in cultivation, though comparatively rare in American collections. These plants need a warm-house, and do not thrive if given too much sun. Full exposure to the light and heat during the summer is not best for them, and though they enjoy liberal watering and syringing when in active growth, discretion should be used or the plants may become sodden and thus lose their roots. When this occurs it becomes rather a tedious operation to restore the plant to health. As to soil, Brunfelsias prefer a light peaty mixture, rather coarse and fibrous, and with good drainage; some lumps of charcoal are a useful addition. The propagation of the Brunfelsias is effected by means of cuttings made of the young growth; these root readily when kept rather close and subjected to a moderate bottom heat. The young plants grow quite rapidly in a temperature of sixty to sixty-five degrees, and the shoots should be pinched occasionally to encourage a bushy habit.

Old established plants will bear severe cutting back to keep them compact in form, as when they are allowed to take their own way they are apt to become rather straggling in appearance.

Regarding varieties it may be stated that *B. calycina* and *B. calycina major* are among the most showy. *B. calycina major* is a garden variety of *B. calycina*, and is quite similar in general appearance to the type, but rather stronger in growth. It bears larger flowers, which are often four inches in diameter, a deep purple color when first open, but fading several shades lighter as the flower ages. The leaves are lanceolate, from four to six inches long and bright shining green.

B. eximia is another fine species, and produces flowers about two inches in diameter and violet in color. The foliage of this species is not so large as that of the preceding, nor so bright, being dull dark green. *B. eximia* is not difficult to manage and continues in flower for a long time, and for this deserves special mention.

A much smaller variety than either of the preceding is *B. uniflora*, which is more useful when small than the stronger growers, from the fact that it makes a compact little plant and is almost continuously in bloom. The flowers are comparatively small, and about the color of a Neapolitan Violet at first, but gradually fade to white, the different colors of the flowers on the same plant having rather an odd effect. This plant is also of some repute in Brazil as a remedy for certain diseases, the roots, and in some instances the leaves also, being used as a medicine, and for this reason it is there known as "Vegetable Mercury."

B. Lindeniana is also worthy of cultivation, and has somewhat similar characteristics to *B. uniflora*, but is larger and stronger. Its flowers are bright purple, with a light centre, and very showy, and the leaves are of medium size, dark green and rather pubescent.

There are several other species which produce quite showy flowers, but those I have mentioned are most easily procured.

Holmesburg, Pa.

W. H. Taplin.

Enemies of Chrysanthemums.

WHILE most of our Chrysanthemums are good, and a few exceptionally so, it is evident that they would have been much better, but for various diseases from which they have suffered. It cannot be true that failure, so frequently reported, is generally the result of carelessness. A good rich soil, when pot-grown, moderately rich when planted out; plenty of water; careful attention with regard to stopping growths, so as to obtain bushy plants; disbudding, to obtain good-sized flowers well distributed over the specimens. These seem to be necessities in cultivation.

The various insects which abstract the juices by means of a beak or proboscis, such as are commonly called chinch bugs, have been numerous as well as various. They appear to have been quite local in their ravages. As was stated by Mr. Jack in a recent number of GARDEN AND FOREST, no external application is of any use in overcoming them except temporarily.

Insects common here could hardly be found in a collection two miles away, where another prevailed which gave us no

trouble. Forty miles away an entirely different insect from either gave the most trouble.

Apart from diseased conditions, which are clearly caused by insects, there are some which are not so easily explained. A number of plants, some of which are now among the best, lost color, that is, went pale, the change being discernible in twenty-four hours. They regained color after two or three weeks without loss of foliage. I consulted several growers, and every one informed me that my plants were either too wet or too dry. I can only say the drainage was good in all cases. I read with interest Mr. Halsted's notes on the Nematodes in No. 138 of GARDEN AND FOREST, and according to his description I am inclined to think some of our plants have the disease caused by them, although I must say that most of the unhealthy plants are those which have been so for two or three seasons. Being good varieties, and some old ones, I have hesitated to throw them away, hoping to bring them into a healthy condition by careful treatment the whole year round. Good healthy-looking cuttings were put in with the others and flourished. All went well until the middle of June, when a few leaves began to wither on one side or at the tip of the leaf, while the base generally remained green and fresh. The affected portion would pass through all the stages of decay, and even after it had dried up the unaffected part would yet be green. A curious thing about this disease is that when once it appears it remains on that particular plant the whole season, and in every case they are old varieties which have exhibited the same disease before. Monsieur Raoux, Daimio, Roseum superbum, Alfred Salter and Talfourd Salter are the greatest sufferers, but neither Jardin des Plantes nor Mrs. George Rundle have done well.

Quite a number of plants have been attacked with a blue aphid on the roots, apparently the variety so destructive among China Asters near Boston last summer. The presence of ants always indicated affected plants. Soot, guano, lime-water (even to soaking the plants in it), sulphide of potassium and magnesium oxide were used against them. The latter compound usually drove the ants away for a day or two, but, likely, only to carry their stock of aphides to another plant, or, perhaps, return. I had an idea that if ants could be banished, successive waterings would fill up the air holes, which they constantly kept open, and so smother the aphides. There is also a roundish, white insect larger than the ordinary aphid, and not unlike what is known as "mealy bug." It is the ants' "cow." I notice now, October, they are busy carrying dead ones to the surface. I have used no insecticides, and do not know whether they have died a natural death or not.

I write of these troubles now in the hope that other growers will give an account of their experience, and perhaps suggest effective methods of treatment against the enemies which seem to attack the Chrysanthemum in increasing numbers every year.

Wellesley, Mass.

T. D. Hatfield.

Ornamental Trees and Shrubs.

ROBINIA PSEUDACACIA, VAR. MIMOSÆFOLIA.—The foliage of this form of our native Locust is of an extremely light and graceful appearance, on account of the small size of the leaflets and their dark and rich shade of green. One would hardly imagine it to be a form of our Robinia at all at first sight. It is most striking in a certain airy character of its foliage, and must make an elegant specimen for a lawn.

ULMUS SINENSIS is a rare Elm, which makes a dense head composed of fine branches and twigs, with its deep green, glossy, acuminate leaves of only two inches in length by three-fifths of an inch in width, closely imbricated or overlapped, in one plane, on the new shoots. It is a tree of very remarkable beauty of foliage, and of as great beauty of outline of the head, when developed. There seem to be several varieties of this or closely related species lately introduced into cultivation, but the form here noted, with foliage lying in one plane on each new shoot, is very distinct and desirable.

A **WEeping PURPLE BEECH**, lately introduced, is proving to be a really desirable tree. Its color is all that can be desired in a Purple Beech, and its pendulous habit is, apparently, an improvement upon that of the well known Weeping European Beech, on account of its regular, upright growth of stem. The irregular form of the old sort is, of course, one of its attractions, but the erect growth of the new variety is in its favor, at least in the practical business of propagating it in the nursery, where the old sort was very unsatisfactory. The side branches have a sweeping and regular "weeping" habit possessed by no other tree.

PTELIA TRIFOLIATA, VAR. AUREA, came out a few years ago, and we have been able to study it under all the conditions of propagation and growth for three years, and it is certainly one of the most richly colored of all the trees and shrubs, having yellow foliage, and keeps its foliage and its high color until into November. Its growth is that of a large shrub, and it can also be grown as a small tree. There is a gloss to the surface of the foliage of the Ptelia, and this serves to bring out the color of this new "golden" sort as varnish brings out the color of painted surfaces, thus greatly enhancing its effectiveness. The yellow or Golden Elder is, by many, considered the finest of that class of foliage plants; but a glance at both these kinds, growing side by side, shows this Ptelia to be very much the richer and more effective. I have never seen the latter burned by hot suns, while the former often gets scorched in midsummer. At this writing, October 9th, our Ptelias are splendid masses of color.

STYRAX OBASSIA has been perfectly hardy here at Cambridge for three years, and now appears to be perfectly contented. Its foliage is oval, or obovate, rugose, of very large size, fully seven inches long by five or six wide, of a light green color. Its blossoms have not appeared here yet, but are described by one who has seen them much in Japan as about one inch across, disposed in racemes eight inches long and very fragrant.

STYRAX JAPONICA, the other Japanese species, has, on the contrary, small and very distinct foliage, with blossoms borne singly and hanging down beneath the rather horizontal branches in the greatest profusion. Both seem to me among the best of the rarer shrubs.

Cambridge, Mass.

F. L. Temple.

Vitis heterophylla, sometimes sold as *Ampelopsis tricolor* or the Turquoise Berry, is a hardy deciduous vine from Japan which deserves a place in every garden, although it is comparatively rare in cultivation. Its habit is similar to that of the Grape, and an established plant will cover a large space with its growth in a single season. The leaves are beautifully mottled with white, while their veins and petioles are a rosy red and the laterals are of the same color. The fruit is small, and it is also variously colored, ranging from a pale China blue to peacock blue, and it makes a beautiful contrast with the variegated foliage. The variegation is more striking on vines which grow in a partially shaded position. It should be planted in a rich loam made light and porous with old mortar or sand. Very little barn-yard manure should be used. Plants trained to pillars, railings or arbors should be cut back hard in winter and tied securely, and the new growth should be allowed to hang loosely where it is not necessary to extend the area it covers; but wherever it can ramble and grow at will it makes a charming picture. This plant is used as an undergrowth in beds of sub-tropical plants in the parks about London with a pleasing effect. It is readily propagated by cuttings from the ripened wood as Grape-vines are. It can be grown also from seed, but this is a much slower process.

Dongan Hills, Staten Island.

Correspondence.

The Hemlock in Eastern Minnesota.

To the Editor of GARDEN AND FOREST:

Sir.—In your issue for October 8th (p. 496) is a note regarding the discovery of the Hemlock in Carlton County, Minnesota, by Mr. H. B. Ayers, at a point farther west than any hitherto known. In Upham's "Catalogue of the Flora of Minnesota" the tree is doubtfully assigned to a few stations, one of which is not far from the place given by Mr. Ayers. The statement is made that they all need verification. Some of the localities are west of the one given by Mr. Ayers, but all of them are not beyond Carlton County. It may be of interest, therefore, to cite some passages from Schoolcraft's "Narrative Journal of Travels from Detroit North-west through the Great Chain of American Lakes to the Source of the Mississippi River in the year 1820" with reference to the presence of the Hemlock in this region. The expedition was under the direction of Governor Lewis Cass and passed through this part of Minnesota. In reading it, the impression is received that the Hemlock was then a common or even abundant forest-tree of the region. The narrative shows throughout that the author was a careful observer and would not easily mistake another tree for the Hemlock. These trees may have largely or wholly disappeared since that time; and if so, it would be interesting to know the causes, if discoverable, for they might have some bearing on forestry conditions and preservation.

It may be only the oft-told tale of destruction by fire and the axe, but if by the latter, the lumbermen ought to know something about it. But from the discovery of Mr. Ayers I suspect that more careful inquiry will lead to finding the tree in other localities, for I shall assume that Schoolcraft knew whereof he wrote.

The expedition went up the St. Louis River, which flows into Lake Superior at its western extremity, then called Fond du Lac Bay. From the St. Louis it crossed over to Sandy Lake, which is tributary to the Mississippi, and is situated in the county next west of Carlton. There it ascended the Mississippi as far as Cass Lake, which it took to be the source of the river. But I find no reference to the Hemlock which could be assigned to a range west of Carlton County, and have noticed none at all in Schoolcraft's account of his expedition in 1832 to Itasca Lake, which, however, is purposely abbreviated where the same ground was traversed. The first mention of the tree which can be assigned to Minnesota is during the passage of the Grand Portage of the St. Louis, the foot of which is placed in the itinerary twenty-three miles above its entrance into the bay. By a chain of rapids and falls the river makes a rapid descent of nine miles, around which boats and baggage had to be carried. Five "pauses" were made the first day of the ascent, a "pause," in the reckoning of the voyageur, averaging half a mile. The next day the party toiled on in a heavy rain, and the journal in part describes their experiences as follows: "We are advancing into a dreary region. Everything around us wears a wild and sterile aspect, and the extreme ruggedness of the country, the succession of swampy grounds and rocky precipices, the dark forest of Hemlock and Pines which overshadows the soil, and the distant roaring of the river, would render it a gloomy and dismal scene without the toil of transporting baggage and the saddening influence of one of the most dreary days" (p. 206). In the journal for the following day (July 8th), on which they halted, Schoolcraft gives a more extended account of the objects of interest observed, quite minutely noting the more prominent geological and vegetable features, as is seen in this extract: "The growth of trees is Pine, Hemlock, Spruce, Birch, Oak and Maple, the former predominating. In clambering among the rocks along the river I found the red Raspberry ripe. This appears to be the common *Rubus strigosus* with a thornless stem; berries scarlet-red, very sweet; akenes lightly adhering. Where depressions exist in the surface of the soil, so that it remains wet and marshy, the Tamarack is found, and the White Cedar is seen overhanging the cliffs on the banks of the river, and adds very much to the picturesque appearance of the St. Louis at this place" (p. 207). From the head of the Grand Portage they go on six miles to the Portage aux Couteaux, the "Portage of Knives," so named because the outcropping edges of vertically arranged layers of slate rock cut the moccasins and feet of the voyageurs making the passage. Its extent is a mile and a half. "The growth of trees here is almost exclusively Cedar, Pine and Spruce."

The difficulties attending the further ascent of the St. Louis being great, Governor Cass sent from this point a party of sixteen, including Schoolcraft and Indian guides, to see if a shorter and more expeditious road did not exist between it and Sandy Lake. The main expedition kept on by the usual route, the exploration by the detachment being for future guidance. But the obstacles encountered seem to have been of a more serious character than those of the ordinary route. It was represented as a two days' journey, but it took the party from the morning of July 10th till noon of the 13th to reach the lake, much of the way being in a very difficult forest. In the account of the first day this description occurs: "Our guides, taking their course by the sun, immediately struck into a close, matted forest of Pine and Hemlock, through which we urged our way with some difficulty. On traveling two miles we fell into an Indian path leading in the required direction, which we followed until it became lost in swamps. After pursuing it two miles, we passed through a succession of ponds and marshes, where the mud and the water were in some places half-leg deep. These marshes continued four miles, and were succeeded by a strip of three miles of open, dry, sandy barren, covered with shrubbery, and occasionally clumps of Pitch Pines. This terminated in a thick forest of Hemlock and Spruce, of a young growth, which continued two miles, and brought us to the banks of a small lake, with clear water and a pebbly shore" (page 210). Two more small lakes were passed soon after, and going on from the last of these for eight miles through a swamp of Tamarack, called by the author *Pinus pendula*, they came to another lake, by which they encamped, the whole distance made during the day being given as twenty miles. My copy of the book is unfortunately

without the map published with it, but from a similar one given in the account of the expedition of 1832, and from the position of Knife Falls, from which they set out, this journey may reasonably be located in the northern tier of townships of Carlton County, or near by. In "Rand and McNally's Sectional Map of Minnesota" four small lakes are found not far apart in Township 49, Ranges 18 and 19, or, since the last stage of the day would indicate a lake somewhat farther off than any of these are from each other, they may have gone farther south into the next tier of townships to a lake near Kettle River.

The next day they went on for nine hours in the swamp, the distance made during the day being given as fourteen miles. It was a very fatiguing journey, under guides uncertain about the way. Schoolcraft gives the following account of some of the experiences of the day: "The dreadful storms which prevail here at certain seasons are indicated by the prostration of entire forests, and the uprooting of the firmest trees. These lie invariably pointing toward the south-east, indicating the strongest winds to prevail from the opposite point. It is one of the most fatiguing labors of the route to cross these immense windfalls. The trees are chiefly Tamarack, Spruce, Cedar, Ash, White Birch and Hemlock. In the course of the day we have crossed a turbid stream running toward the south, called Akeek Seebe (Kettle River), which is tributary to the Missisawgaiegon, which enters the Mississippi a short distance above the falls of St. Anthony, after having passed in the intermediate distance through the Great Spirit Lake" (page 214). This is in part a geographical error, as no rivers from this region go into the Mississippi except by Sandy Lake or the St. Croix. But Kettle River is tributary to the St. Croix, and it rises in the northern tier of townships of Carlton County not far west of the lakes mentioned above. This is the last mention of the Hemlock in the narrative as far as I have observed. On the 12th they went on for twelve hours in the swamp, emerging at nightfall, and encamping by a small stream called "Buffaloe Creek," tributary to Sandy Lake, which was reached the next day.

The body of the expedition continued their course up the St. Louis to the mouth of the East Savannah River, and by this and the West Savannah passed over to Sandy Lake. Schoolcraft requested Dr. Wolcott, physician of the expedition, to act as naturalist in his absence. It is not definitely stated in the short account he gave that the Hemlock continued to be found, though it may be included in the statement he makes that the banks of the river above the Portage aux Couteaux were "always covered with a thick growth of Birch, Elm, Sugar-tree (*Acer saccharinum*) and the whole tribe of Pines, with an almost impenetrable thicket of underbrush." Most of the botanical writers of the time included the Hemlock, Spruces and Firs under the genus *Pinus*.

From these extracts and statements it is safe to conclude that the Hemlock was a well known tree in this region in 1820, and that it extended, at least, well toward the western limits of the territory now included in Carlton County. And I may add that in going northward from Duluth to Two Harbors by the shore of Lake Superior, in the summer of 1889, I thought the Hemlock was one of the trees observed from the cars while passing. But in this I may have been mistaken, though I have reported the tree as present there. In a doubtful case thorough identification would demand closer inspection of a tree than can be had when the observer is in rapid motion. But as the Hemlock is reported by Agassiz among the plants of the northern shore of Lake Superior, it is not unreasonable to suppose it may be found at its western extremity. In his list of plants gathered, and given in connection with the topic headed "Observations on the Vegetation of the Northern Shores of Lake Superior" (page 165), he names no locality for the Hemlock, so that it is not easy to determine how far west it was found, the expedition having gone as far as the Victoria Islands, or nearly to the United States boundary, before turning homeward.

It might be deemed more satisfactory if Schoolcraft had somewhere given the botanical name of the Hemlock, as he does at times of other plants. But I do not find its scientific name in any of the three volumes of his explorations in this section or immediately south. But the *usus loquendi*, both in common and scientific language, at the time, is sufficient proof that the Hemlock-Spruce (*Tsuga Canadensis*, Carrière, *Pinus Canadensis*, Lin., and authors) was meant. As the equivalent of *P. Canadensis*, Hemlock, or more commonly Hemlock-Spruce, is given by the following authors about that time: Pursh (1814), Nuttall (1818), Barton (1818), Elliott (1824)—a list not intended to be exhaustive, but representative.

Englewood, Chicago.

E. J. Hill.

Periodical Literature.

WE are pleased to find in the November number of the *Century Magazine* an editorial article entitled "Forestry in America." So clear and sensible a paper would have been pertinent and welcome at any time; but it is doubly valuable now, following as it does the articles by Major Powell in the same magazine, to which we have referred as likely to exert a pernicious influence on the public mind.

It is not needful that we should quote largely from the article. It simply rehearses facts and voices sentiments with which our readers are familiar. It speaks of the non-existence as yet of any real science or practice of forestry in this country, of the need for this science and practice, of such local efforts as have been made to preserve forests and beautiful tracts of landscape, and then, at some length, of the value of the forests on our public domain to the American people at large. The suggestion made in these columns, that until some more adequate means is provided the army should be used to preserve these forests, is endorsed, and an especially good point is made in the recommendation that, among spots which should in some way be forever preserved for public use, tracts of sea-shore ought to be included. This point has hitherto, we think, been overlooked in theoretical expositions of the importance of establishing parks and reservations of different kinds; but, as the writer says, "unless there is prompt action in this direction our children will probably live to see the shore-lands everywhere enclosed, and in many places a fee demanded for a good view of the ocean, as we had to pay to see Niagara until the state of New York made that scene of beauty and grandeur a public possession and forever free to all."

After describing the way in which forest-destruction influences a country, the editors say: "All this is known. It is not a matter of theory, probability or opinion. It has been incontrovertibly established by repeated observations in all the mountain countries of the Old World and in our own. The results are uniform. No exceptions have been observed, and there is no question or doubt regarding these destructive tendencies and effects among those who have observed the facts which are everywhere palpable in this department of nature and of human experience. Those who know anything of the subject are agreed that, in general, the forest-clothing of mountains cannot be permanently removed without far-reaching evil results." This is proof that, although they gave him the opportunity to explain a personal point of view, Major Powell's conclusions and desires are not endorsed by the editors of the *Century Magazine*.

Exhibitions.

Chrysanthemums at Short Hills, New Jersey.

THE blooming of the Chrysanthemums was the occasion of Messrs. Pitcher & Manda's autumnal flower show last week. The exhibitions at the United States Nursery have always been interesting, and with the continued growth of the establishment seem likely to become prominent attractions to local flower lovers. I found on a visit to Short Hills the main crop of Chrysanthemums in full bloom and the show-house arranged much more attractively than last year, when a large bed of the Mrs. Alpheus Hardy occupied the entire centre. This had given place to a fine arrangement of Palms, Tree-Ferns and other decorative plants, not only attractive of themselves, but presenting a foil to the great masses of flowers which were banked on all sides. A noteworthy (it might be said to be novel) feature was the arrangement of the flowers in harmonious color-masses, each color near its complementary one and the magentas at safe distances from the oranges. Messrs. Pitcher & Manda seem also to have arrived at the sensible conclusion that naturally grown plants, judiciously, but not severely, disbudded, and cultivated only enough to bring out the individual characters of the flowers, are such as are most appreciated by the public. While they showed many fine exhibition blooms to interest the fanciers of the flowers, the main display was made up of great masses of medium sized flowers, the effect of which was very pleasing, and, what was more to the point, as the exhibition was for prospective profit, those who intended to purchase could note the true characters of the different varieties under such cultivation as would not be beyond the skill of an ordinary grower. Exhibition blooms are superb, but misleading to the inexperienced.

One of the most striking features of the collection was the surprisingly large proportion of kinds which were either seed-

lings raised by Pitcher & Manda, or had been introduced by them, most of them of very high character. Good examples of their 1890 varieties were shown, including Shasta; Mrs. Hicks Arnold; Mrs. Grace Hill, creamy pink, fine incurved; Jean Humphrey, fawn; Rohallion, very distinct chrome-yellow; and Elliot F. Shepard, lemon-yellow.

A very large lot of seedlings were showing their first blooms, and there were many promising ones among them, mostly unnamed as yet. I noted Dr. H. A. Mandeville, a clear yellow Japanese reflexed, very deep and full; Number 65, a white, hairy kind, which seems to possess some points of superiority over Mrs. Hardy, and with the same habit; Number 30, a yellow Anemone, large, with very long guard florets, very distinct; Number 24, a large, pure white, reflexed kind; Number 165, a pink one of the same style; Mrs. E. D. Adams (white), George Savage, Hicks Arnold (old gold); but these are only a few of their coming novelties. Not to enlarge on the numerous distinct flowers, mention must be made of W. A. Manda, a seedling with extra long hairs and a dark color, but not yet perfected enough to describe.

Chrysanthemums occupy but a small portion of the nursery, for long ranges are full of Palms and decorative plants of choicest kinds in great variety, every important family having a specially arranged section. The *Cypripedium*-house, which contains probably the best collection in the country, was in fine bloom, and would well repay a journey. On the stages were many fine Cattleyas, *Oncidiums* and *Vandas*. *Nepenthes* occupied spare roof room, while *Anthuriums* brightened up odd corners. Messrs. Pitcher & Manda have engaged the large hall of the Madison Square Garden, and propose giving a grand show of Orchids, decorative plants and late Chrysanthemums on Thanksgiving week and the following Sunday and Monday. The transportation from such a distance, and at this inclement season, of enough plants to fill so large a space as the Madison Square Garden seems like a great undertaking; but if the charming display of last week can be successfully transferred to the city, we shall have one of the best floral shows yet given here.

Orange, N. J.

G.

Chrysanthemums at Orange, New Jersey.

THE New Jersey Floricultural Society held its fifth annual Chrysanthemum Show in Orange last week. This is an exhibition which usually excites sharp competition on account of the liberal prizes offered, and brings together large displays from the numerous growers of the favorite autumn flower. The show this year was noticeable for some fine exhibits of new seedlings and cut blooms and the remarkable dearth of specimen plants. A Chrysanthemum show without great masses of plants and profusion of bloom is somewhat unusual. The indications are that this season will prove a great one for new seedlings of merit. Many were exhibited here for the first time. The Pitcher gold medal for best seedling plants was awarded to Mr. John Thorpe for his seedling, George W. Childs, a fine flower, full and deep, of a rich dark crimson, a color rare among Chrysanthemums. The habit is sturdy and the plant of medium height and very vigorous. Among a number of Mr. Thorpe's seedlings, Ernest Asmus, a fine bronzy chrome, was specially promising. The Pitcher silver cup for six best seedlings was taken by Mr. T. H. Spaulding with Ethiopian, Ethel Paul, John Firth, Lily Bates, Onward, Mrs. D. D. Farson. This was a grand lot of blooms, the latter especially having a flower of distinct form and good color, which may be called "La France pink." Messrs. Pitcher & Manda had a grand stand of flowers not in competition. Some of these were Mrs. Grace Hill, Dr. H. A. Mandeville (yellow), D. S. Brown (lemon-yellow), George Savage (white, seedling from Mrs. Hardy) and Hicks Arnold (old gold). They gained first premium for a seedling plant of Mrs. E. D. Adams, a very full white, somewhat in the way of Madame C. Audiguier in form.

William Tricker took first prize for fifty varieties of cut blooms, among which specially noticeable were Mrs. A. C. Burpee, Ada Spaulding, W. W. Coles, Eldorado, Excellent, Ivory, Mary Wheeler, Lilian B. Bird, Japonaise, Eynsford White, Sunflower, G. P. Rawson, Mrs. Irving Clarke, Mrs. Benjamin Harrison, Rohallion. The second prize in this class went to T. H. Spaulding. His best flowers were of Challenger, Cyclone, Mabel Ward and E. G. Hill.

The first prize for twelve blooms was taken by Ernest Asmus with Harry Weidener, J. C. Price, Sunnyside, La Fortune, etc., and William Tricker carried the second.

The first prize for six blooms went to William Tricker with Excellent, Grandiflorum, C. Orchard, Mrs. De Witt Smith, Ada Spaulding, Superbe Flore. The same grower also took first

prizes for the best twelve Chinese incurved and six Anemones, neither of which were up to first-rate standard.

A silver cup was awarded J. N. May for the best display arranged for effect—a good arrangement it was with autumn foliage.

In standard plants, John Farrell, gardener to Mr. Wm. Barr, took first prize for a lot of five-foot plants with flat trained heads—a very uniform lot, but not as useful or pleasing as the standards with untrained heads formerly exhibited by Mr. Farrell. A plant with a flat top, blooming at a height just above the vision of an ordinary observer, does not seem specially desirable, but will probably be grown as long as societies offer prizes, especially as with these the grower has no difficulty with the foliage so hard to retain on pot plants.

Low-grown plants and bushes were very few and ordinary. Mr. Farrell worthily gained the first prize for fifty plants in six-inch pots with single stems, with the best lot ever shown in this locality—grand blooms and perfect foliage. T. H. Spaulding was second in this class with a good lot.

Miscellaneous collections comprised groups of Palms and decorative plants, with a fine new *Alocasia* from Pitcher & Manda. A superb lot of Roses from Mr. J. N. May showed perfect blooms of Duchess of Albany, Ma. Capucine, La France, Catherine Mermet, Bride, F. Bennett, American Beauty and others. The new Rose, Waban—the “Red Mermet”—was on the same stand, and attracted much attention by its beauty and evident value.

Mr. H. A. Dreer exhibited a new Hybrid Perpetual Rose (unnamed) of great promise—a clear, bright rose in color. A horticultural exhibition would be incomplete without a few curiosities, and this contained the saddest examples of trained *Chrysanthemums* probably ever shown. An ingenious, not to say a misguided, grower, exhibited a series of plants the heads of which had been patiently trained to spell out his full name. Before casting too many stones at him would it not be well for growers to ask whether this is not the natural outcome and final result of the trained *Chrysanthemum* habit?

Newark, N. J.

Notes.

The American Florist will hereafter be published every week. Its editor announces that it will remain strictly a trade paper, but it always contains matter of interest to readers who are not commercial florists.

It is reported that in many parts of Nebraska, from which large exports of corn were made last year, the present crop will not suffice for home feeding. This loss was caused by the severe drought.

A sweet-scented Rose “of a steel-green color” has, according to accounts in foreign journals, been produced “after experiments lasting many years” by Dr. Bonelli, of Turin, and has been named by him the “Edison.”

A recent writer in *Fire and Water* says that German chemists have discovered a means of preparing wood so that it becomes as indestructible as brick. A large hotel has just been built in Hamburg “entirely of blocks of compressed wood as hard as iron, and, by subjection to certain chemical processes, rendered proof against both fire and the attacks of insects.”

It has long been the custom to give away to the public, in autumn, many of the plants which have been used in the “pattern-beds” of the Boston parks; and this autumn the same practice was commenced by the Commissioners of Fairmount Park in Philadelphia. This is certainly the best way to dispose of such superfluous stock, although it may tend to foster an undue desire on the part of the public for the perpetuation of the bedding-out system.

The beauty of a Chinese Oak (*Quercus Chinensis*) at this season of the year is worth noting. It is a tree from the northern parts of China, which was introduced several years ago by Dr. Bretschneider into the Arnold Arboretum, where it is perfectly hardy and is growing rapidly. The leaves at this season of the year turn bright canary yellow, like those of some Hickories and some individual Sugar Maples—an autumn color entirely unlike that assumed by any of our native Oaks.

In a conversation with a reporter of the New York *Tribune*, Mr. Charles A. Dana, who has just returned from a trip through south-eastern Europe, said that one of the things which had struck him most forcibly was the great extent of the cultivation of Indian Corn in Hungary, Roumania, Bulgaria—in short, with the exception of Greece, throughout south-eastern Europe; he had never seen in the western states of our coun-

try such immense fields of Corn as in these countries. “I should say, in fact, that in a continuous journey of 600 or 700 miles we saw nothing else except as a mere incident. The Corn makes the great mass of agricultural industry.”

It would be difficult to name a shrub whose foliage turns to more brilliant colors in autumn than the Swamp Blueberry—*Vaccinium corymbosum*. It has the merit, too, of retaining its rich colors for a much longer period than most other trees and shrubs. It is still attractive, although it began to turn more than a month ago. *Rhus copallina* is another native shrub whose leaves remain a deep crimson for four or five weeks. This persistence of autumn color, as well as its brilliancy, should be taken into account when the comparative value of ornamental trees and shrubs is estimated.

Foreign journals are never tired of recounting the strange freaks of taste to which they suppose the American public gives way. The last report of this kind comes in a recent number of the *Illustrirte Gartenzeitung*, of Vienna, where we are told that “stewed Lilies” are now a recognized article of diet in this country, and that a favorite delicacy is “Rose cake,” in which layers of cake alternate with layers of stewed fruit and of Rose-petals. It is furthermore said that American ladies are in the habit of administering to themselves hypodermic injections of perfume, and of varying the essence chosen so that their morning differs from their evening odor!

The paper contributed by Dr. M. T. Masters upon the comparative morphology, anatomy and life history of the *Coniferae* to the *Journal of the Linnaean Society* has now been issued separately. This is a most important contribution to our knowledge of the cone-bearing trees, and is the result of personal observation and research carried on by the author during many years. The object of the investigation, he tells us, “has been to gain a general and comparative view of the external morphology of the whole order, to ascertain so far as possible the causes and conditions inducing the development of particular forms or modes of growth, and to inquire into the purposes of the numerous variations and presumed adaptations.”

Mr. E. P. Powell writes from Clinton, New York, under date of November 1st: “I have to-day picked from a Mazzard Cherry-tree good, sound, delicious cherries, grown in my garden. The tree was covered, just after the cherries began to color, with mosquito netting to keep off the robins. Heretofore I have finished my cherries a good deal earlier; but having five trees covered, saved one to find out how long the fruit could be preserved. The cherry will hang in good condition all summer on the trees, and be fit for use till October, or, as I have now proven, till November. There will be some rotting after September. The fruit is to me so fine and wholesome I am willing to be at some cost to have it for five months.”

Mr. James Mooney, who devoted much time to studying the Cherokee Indians, says that the aggregate botanical knowledge of their doctors embraces about 800 species of plants, although no one doctor knows the names of more than 300 species. As many as 2,000 species flourish in the regions of western North Carolina where the Cherokees have dwelt, but they have no names for even the most conspicuous flowers unless the plants are used as food or medicine; and Mr. Mooney concluded that they had no appreciation for beauty or fragrance as such. Nevertheless they must appreciate some of the qualities of plants in a semi-poetic, semi-superstitious way, for we are told that part of the ball-players’ training is to assimilate the strength of Iron-wood, the toughness of the roots of *Tephrosia Virginiana* and the persistent erectness of a Rush by bathing themselves in decoctions made from these plants.

About thirty persons responded to the invitation extended by the State Forest-Commission to members of clubs and other associations owning land in the Adirondack region to meet them at an informal conference upon matters relating to the establishment of the proposed Adirondack forest-park. All who spoke considered the establishment of such a park desirable, and most of them agreed that the first object should be the protection of the sources of the Hudson River and other streams which rise in the mountain forests. The value of the wilderness as a sanitarium, as a place for summer rest and recreation, as a hunting ground and a preserve for fish and game, was also recognized. Another conference will be held at the office of Mr. Knevals, 32 Nassau Street, in this city, on November 19th at eleven o’clock in order to obtain further expression of opinion as to the best location of the park, its extent, the most feasible method of obtaining the land required, and what should be done in relation to the area owned by clubs and other large holders.

The Cultivation of Asparagus in France.

IN no other special culture do the French surpass to such a degree the rest of the world as in that of Asparagus. Not only is the best Asparagus raised in France better than the best of any other country, but the quality of the French crop as found in the French markets, not only in Paris, but all over the country, is far superior in quality to the Asparagus sold in the markets of other countries.

The excellence of French Asparagus is secured by the most careful and systematic cultivation, and as the French methods differ so materially from ours, especially in the practice of allowing the crowns to freeze in winter, while in this country it is an almost universal custom to protect them by a heavy mulch of manure, and in the summer fertilization of the plants, that we have asked Monsieur Henri L. de Vilmorin, who speaks of French vegetables and French methods of cultivation with the fullest knowledge of the subject and the highest authority, to describe for the benefit of our readers the methods by which the best French Asparagus is produced. The following description from his pen will be read with interest by American gardeners:

Whatever is worth doing at all is worth doing well. To no subject can that old saying be more justly applied than to Asparagus-growing, as not only is proper care a necessary condition of success, but the superiority of well grown to poorly grown produce is perhaps greater in the case of Asparagus than in any other vegetable. Both the eating quality and the market value of a bunch of Asparagus increase very rapidly with the size and beauty of the individual shoots that go to form it.

Asparagus officinalis, a native of south-western Europe, is perfectly hardy all through France and Great Britain, and will prove so over nearly the whole of the United States, where, with proper care, it should be possible to raise as fine specimens as any that are grown in Europe. In fact, Asparagus being a spring vegetable, the crop can be ready and even over everywhere before the summer heat and drought set in.

Planting the roots far apart and not too deep, and then manuring heavily and repeatedly, are the great points in the most successful Asparagus-gardens in France; and these points are, in my opinion, those that need to be brought most forcibly before the American Asparagus-growers.

Any soil which is not stiff, adhesive clay, nor pure, dry chalk, can be rendered proper for Asparagus-culture by draining, trenching and manuring. It is necessary that a depth of from one foot to a foot and a half of perfectly drained soil be secured under the surface, but this is amply sufficient, since Asparagus develops no tap-roots. Light sandy soil is quite good if properly manured.

In France it is usual to trench and manure in the fall with common stable-manure the plot which is to be planted out to Asparagus in the spring. In very light soil cow-manure is preferred. In March the rows or beds are marked out, the position of each set being indicated by a small stick placed in the ground. One or two-year-old seedlings are generally used as sets. They are never planted at a less distance than two feet each way. For exhibition purposes plants are set three and even four feet apart.

At the place where each little stick stood a small conical heap of compost or mould from thoroughly decomposed manure is made, and the centre of the crown of the set is placed on top of it, the fleshy roots being spread, radiating in all directions down the sides of the small hill. The roots are then covered with additional compost or mould, one or two large handfuls being used on each set; the roots only, and not the crown, being so covered, the hills are made larger, but not higher, by the process. Loose soil is then filled in between the hills and level with the crowns of the sets. This soil has been prepared by scraping the surface of the beds three to four inches deep before marking out the place for the sets and by heaping the loose soil in the walks between the beds or the rows.

After the first summer and fall, when only weeding, and, perhaps rarely, watering has to be done, the surface soil is in the month of October scraped off between the plants and made into a ridge in the walks, as was done before planting. The roots are by this means brought close to the surface and submitted to the action of cold air and frost, which, at least in Europe, seem to benefit them rather than otherwise. Only experience can show whether the same system would be equally advisable for America, where the winters are so much colder.

Manure is spread the second spring on the roots mostly in the shape of mould from town scrapings or from decomposed stable manure. Common salt may be added with good results in places where it is deficient in the soil. Then the loose soil is again filled in on top of the manure and between the plants so as to make the surface even.

The next year the same processes are repeated, but the loose soil is heaped to a greater height, in a conical hill one foot high, over each Asparagus plant, as from this, the third spring, one or two shoots can be cut from each well-established plant. The hill formed on top of the crown is intended to bleach the shoots and to force them to become longer. After the cutting season is over (which should be about May 15th on the year of the maiden crop and June 15th on succeeding years) the mounds of soil are to a great extent scattered and spread in between the plants, all the shoots produced later being allowed to grow and develop into leafed stems.

Afterward the routine of the cultivation remains the same, manure being added at least every second year, and either in the fall, in winter or in early spring, in fact at any period between the time when the surface soil is scraped out and the time for spreading it on again. The number and beauty of the shoots go on increasing for the three or four first crop years, and then the plantation can be kept at its best for five or six years more by liberal and repeated manuring.

Great care is exercised now, in France, in gathering Asparagus-shoots to break them clean at the point of insertion on the crown, and not to cut or saw them off. The latter practice had the two-fold fault of leaving on the plant old stumps which decayed and often induced rotting of the crown itself, and besides it frequently occurred that undeveloped or partially developed buds were injured by the knife and destroyed. At the present day the most approved practice consists in throwing back with one hand the soil of the hill, while holding the shoot with the other hand and in following it down to its base, when it is easily broken off clean by bending it on the side on which it was laid bare. The hill is then immediately formed again as before.

All this care and labor might justly be considered excessive were 200 or 300 shoots required to make a decent dish, but they can well be afforded where fifty make a very large one.

The taste for almost white asparagus, with only one inch or so of purplish top, is prevalent in France, but the shoots may be allowed to grow a little longer and greener when they are preferred so.

It should be added that asparagus, to be at its best, must be gathered only a few hours before it is cooked. In most cities and towns there seems to be an unlimited demand for asparagus, fine, medium, and even poor. Still good fresh specimens always command a much higher price than small wiry ones, or than asparagus brought from a distance.

THE general ignorance which prevails in this country with regard to trees, and especially with regard to the simplest phenomena of their lives, is always a matter of surprise to the few persons who study the different phases of tree-life and look on the trees they pass in their daily walks, or in longer journeyings, as old friends and companions. We recall the instance of a person of more than ordinary intelligence and cultivation, possessing the instincts of a naturalist, shown in an unusual love of animals and in a fondness for studying the habits of bees, ants and other insects, and who, moreover, was bred in the country. This person, when past middle life, learned for the first time that Oak-trees had blossoms and that the cones of the Spruce had grown from flowers. Trees had been taken as a matter of course, and passed by year after year without a thought bestowed upon the secrets of their existence. The individual flowers of the Oaks and Walnuts, the Beeches and Alders, the Birches and Hornbeams, the Pines and Spruces, had never been seen, and the beauty of their marvelous structure had never been so much as dreamed of.

That ignorance of this sort is not unusual is shown by the fact that we find in common use the terms "flowering trees" and "forest-trees" employed as if some trees, like the Apple or the Locust, produced flowers and others growing in the forest did not, and this by authors from whom better things might naturally be expected. All this only goes to prove that we in America need more instruction about our trees than we are in the way of obtaining. Some accurate knowledge of the common trees which surround our homes and make up our forests should form part of the mental equipment of every educated man and woman. Knowledge of this character adds immensely to the pleasures of life. Once gained it is never lost; and the field is never exhausted, for there is always something new to learn about a tree.

This is a subject of wide-spread and practical importance. Trees collectively, that is when they form forests, have an important influence upon the destiny of the human race. Americans are destroying their forests with a recklessness unknown to any other people. This recklessness is the result, in a large measure, of ignorance, and if the value of our forests is ever really understood it will be through the intelligence of the individual trained to appreciate them. How can this intelligence, which, if once acquired, will, perhaps, eventually make the protection of forests possible through wise and far-seeing legislation, be developed? There is certainly no more practical way to begin than by teaching the children of the country something of trees. Knowledge in such matters, especially if acquired early, begets affection, and affection for the individual tree as a tree once fixed, it will be a comparatively easy matter to build up in a community, trained from childhood to love trees, an intelligent interest in the forest in its practical relations to humanity.

Field Notes from the Colorado Desert.

ON the 15th of September I left San Diego by rail for Yuma, Arizona, to make botanical collections in the region generally known as the Colorado Desert, in south-eastern California. At Yuma I found that the season had been slightly drier than usual, and there was scarcely any vegetation except along the banks of the Colorado River. I had the pleasure of experiencing one of the heaviest rains of the season, a brisk shower that lasted about half an hour, accompanied by considerable wind.

Opuntia tessellata was fruiting on the hills near Yuma, and I have since found it in various portions of the desert. The fruit is small, dry, with comparatively few large seeds. This

and one or two other species of the same genus were the only Cacti seen on either bank of the river, except a few transplanted in gardens and a single beautiful plant of *Mamillaria*, found on the sandstone hills south of Fort Yuma, in San Diego County, California.

From El Rio Station, on the Southern Pacific Railway, I walked southward over the hills bordering the Colorado River to Hanlon's Ranch, better known in former times as Hanlon's Ferry. The old station-house, on a rocky bluff at what was once the ferry landing, is now over a mile from the river bank, the river having cut its way to the eastward. This new-made land is subject to an annual overflow and is extremely fertile. It is grown up to a forest of Cottonwoods, Willows and Mesquite-trees of magnificent proportions, and the growth of underbrush and other vegetation is very luxuriant.

Mr. Hall Hanlon, one of the few remaining pioneers of early days, since the advent of the railroad has turned his attention to stock-raising and horticulture. He has been the first to demonstrate the practicability of cultivating the Date in the Colorado Desert. In 1884 he had fully a hundred Date-trees nearly ready to bear, but, unfortunately, an overflow of the river on his land and a combination of other disasters, nearly destroyed them. The Date comes into blossom in five years from setting on his ranch, and he had a supply of fruit in eight years from the planting of the seed. He has two varieties in bearing now, one with large yellow fruit, and a smaller kind with beautiful, rounder, reddish fruit, which at the time of my visit hung in tempting clusters from the trees. Hundreds of offshoots from his trees he has planted out, and in a few more years he could have one of the most profitable and novel of California orchards, or fruit ranches as they are generally called. Other experiments in the culture of the Date were soon to be made near Yuma, Arizona, in the Gila River Valley, which is very aptly called the Gila Desert to distinguish it from the Colorado Desert that lies west of the Colorado River.

Traveling westward from Fort Yuma I found an almost unbroken, barren plain, destitute of verdure until near Indio, in the north-eastern portion of the region. In the Cargo Muchacho Mountains, where several gold mines are being developed, I found it equally uninteresting from a botanist's point of view, except where the "tailings" and waste water from the quartz mill were allowed to flow. A few grasses, one or two introduced weeds and a number of wild flowers—several new to me—were thus caught out of season.

Indio, and the section of the desert to the westward, is probably the best known portion of the region as far as its botanical resources and horticultural possibilities are concerned. The Washington Palm-trees, on the open plains and on the sides of the mud hills to the northward, form one of the most interesting features in the landscape, since the Californian Fan Palm elsewhere is of a more retiring disposition, seeking the seclusion of rocky and almost inaccessible cañons. Some of the Palms grown in the grounds around the railroad hotel at Indio are of most luxuriant growth—a single leaf almost sufficient to shield a standing man from observation!

On the 1st of October I again set out for the southern borders of the desert with a two-horse team. The reports of the great overflow of the Colorado River, through the New River section, had been confirmed by reports received at Yuma, and it was with a view of securing the consequent vegetation that I undertook this trip. It has been six years since the last great overflow occurred, in 1884, and the chance offered by the June and July overflow was one not to be neglected. La Laguna Maquata, a shallow basin just south of the United States boundary, usually dry, was also reported full of fresh water from the same overflow, and said to be teeming with fish. No water has been known in this lake since 1884 either, and here was another opportunity.

At Mountain Springs we filled all our water-cans, fearing that this might be the last good water we should find, and it proved fortunate that we took the precaution. At Coyote Wells, fifteen miles distant, we found the water unfit for man or beast, but by digging a new well we were able to secure a limited supply of strong alkali water, which we ventured to give our horses. The only feed was some Gietta Grass, about two miles distant from our camp. Proceeding in a southerly direction from Coyote Wells we traveled over a sandy, rolling country to a point in the Maquata Basin between the Cocopah and the main peninsula-range of mountains. The western shores of the lake were dry and strewn with millions of fresh water shells, which encouraged us to expect to find some fresh water. Along the sandy arroyo leading to the lake were numerous beautiful Ironwood-trees, fifteen or twenty feet high, and nearer the shores of the lagoon were bush-like clumps

of Mesquites, around which the sand had blown into mounds or small hills. Nearer the lagoon the Mock Willows (*Pluchea borealis*) gave evidence of fresh water, which could, doubtless, have been obtained at less than twenty feet by digging. *Sesuvium portulacastrum* and a few other saline plants were also very abundant; but these comprised nearly the whole of the vegetation discovered along Maquata's shores.

A beautiful mirage led us away from the actual water, and upon learning its delusive character we became skeptical as to the existence of water in any part of the lake. Although I had often seen this phenomenon on the desert I had never before been led astray. In the evening, however, we were enabled to distinguish the true from the false, and found that the eastern part of the lake, for many miles to the southward, actually contained water. On the mesa west of the lake we made our camp, about three in the afternoon, where there was an abundance of Gietta Grass (*Hilaria rigida*) for our horses. Leaving my companion to care for the team, I started on foot to search for water in the cañons leading down to the desert from the main range of mountains, but failed to discover any up to seven o'clock, when it became too dark to proceed, and I was reluctantly compelled to retrace my steps as best I could. My landmarks, the mountains, were soon indistinguishable, but taking my bearings from the stars I got back to camp soon after eleven o'clock after an eight hours' tramp.

Before sunrise in the morning we were again en route to the lake, and after two hours' travel arrived near the edge of the water. With difficulty I reached the water through the soft mud, and found the water so shallow at that place that I had to dig a small hole before I could dip up any to taste—and then I found it to be nearly as salt as brine!

With our water supply nearly exhausted, the temperature at 105 degrees Fahr., and thirty miles from any sure source of water, we considered it only prudent to return to Coyote Wells while we could. For two days our food had consisted mainly of hardtack, and on our return to Coyote Wells the wind prevented our cooking a good meal until the following afternoon.

From Coyote Wells we have moved to Dos Cabezas, where there is an abundance of water, and we are partially sheltered from the wind and rain. It is necessary to pile rocks on the blankets to keep our bed from blowing away with us, and the wind blew my loaded wagon a considerable distance during the night. The sun is shining brightly as I write, but before I finish this sentence the black clouds hanging over us to the westward will have flung us in the shade again. From tropical heat we now find a fire-place a comfort.

Whether reports concerning New River are equally as trustworthy as those relative to Lake Maquata we hope to decide later, but it is necessary to haul water for fifty miles at least to settle the question, and to be prepared to return if we do not then find it. These are some of the pleasures of botanical exploration in our great arid regions.

Dos Cabezas, Colorado Desert.

C. R. Orcutt.

Lumbering in Michigan.

SIXTY years ago Michigan was almost entirely a wilderness, and a good portion of it was covered with virgin forests. Nearly all of the southern half of the southern peninsula abounded in deciduous-leaved trees, while north of this were large tracts of Pines and other conifers, or a forest of conifers and deciduous trees mixed in varied proportions, or there were some large areas consisting entirely of deciduous trees.

The pioneer, finding no market for his timber, used a small portion only of the very choicest for his limited needs in building and fencing. He cut and burned, hewing for himself a home out of the forest, making room for cultivated fields in place of trees. Gradually, but slowly, a market was found for timber. At first, only the best cuts of the choicest trees could be sold at any price. In southern Michigan, about the year 1850, I drew for my father many loads of the choicest clear stuff of Whitewood or Yellow Poplar (*Liriodendron Tulipifera*) fifteen miles, where it was sold at \$5 per 1,000 feet, and the pay taken in goods at a country store. Even this market was limited, and was found in the Oak-openings. There was not much money in lumbering in those days. The trees, though, had to be got out of the way and made to bring what they would.

It was scarcely more than ten years later (1860) that in the same region farmers had nearly ceased burning log-heaps and had begun to make use of all the timber taken from new land for lumber, rail-fences, fire-wood for themselves or their neighbors or for the nearest village or railway. This was in a country long since noted for its good land and prosperous

farmers. In fact, Lenawee County, Michigan, is known to be one of the very best "all-round" counties in the United States for diversified agriculture or mixed husbandry.

In newer portions of the state, many parts of which for some reasons were less suited for agriculture, the removal of the timber has been at a much slower rate. It is now as rare a thing as it was common once to see Hemlock-trees felled and left to rot or burn on the ground, simply to secure the bark for the tannery. The hard wood is now, in 1890, nearly all saved, even in the least settled portions of the state, for lumber, for the railroad or for charcoal. Still there are a few places, remote from market, where the tops, butts and deformed sticks of soft wood or hard wood are not very closely used up, but are allowed to decay on the ground.

When good farming land, or poor land that is covered with desirable timber, has once passed from state control the owner feels that something must be done with the timber very soon to prevent a losing investment. It has usually been the experience of Michigan men that it has not been profitable to hold timber for higher prices, and few people will attempt to hold it simply for the good of the township or state or for posterity, under such circumstances. Had a much larger proportion of the timbered land been held and protected by the Government for a longer time the state would have been much better off in the end. Less timber would have been destroyed, the land that was improved would have been better worked at a greater profit. This is a lesson which should be heeded in the more recently settled portions of the country.

There is too much risk from fire in most places in Michigan to make it wise to hold for a very long time any large amounts of land covered mainly with evergreen trees. Where there are a few evergreens mixed with forests of deciduous trees the risk is very greatly reduced.

The illustration on page 563 shows what remains after fire, following the axe, has run through the woods and consumed the smaller branches. Sometimes the logs are brought together in heaps and burned, or allowed to gradually disappear by a combined process of decay and repeated burning.

The Lakeside Daisy.

AN interesting item in the botanical record of the season is the finding in Ohio of an *Actinella*, which seems to have strayed away from its home in the west. Mr. Clarence M. Weed, of the Ohio Experiment Station, gives the following account of the matter, which we take from the *Journal of the Columbus Horticultural Society*. Accompanying the article is a good figure of the plant, *Actinella acaulis*, from a drawing by Miss Freda Detmers.

Early last May while collecting botanical specimens in northern Ohio, on the limestone plains of the Sandusky Peninsula, near Lakeside, I came across many large patches of a very pretty bright yellow flower, which formed by far the most striking element of the local flora. It proved to be *Actinella acaulis*, Nuttall, the ordinary home of which, according to Gray, is found on the "Rocky Mountains and bordering plains and hills, Dakota to Montana, and south to New Mexico, western Nevada and Arizona."

Not only is this particular species a western form, but *Actinella* as a genus is essentially western. Its representatives occur especially in the rocky prairie and mountainous regions of the extreme western states: Dakota, Montana, Colorado, Texas and New Mexico are the homes of many species. According to Gray's "Synoptical Flora" the only known occurrence of a member of the genus east of the Mississippi River is that of *A. acaulis*, variety *glabra*, which was found many years ago on "an ancient mound at Joliet, Illinois," and its occurrence was said to be "probably adventive."

In northern Ohio *A. acaulis* is thoroughly established, and evidently finds on the barren limestone plains, with their two or three inches of soil, a congenial habitat. Dr. C. E. Bessey tells me that in Nebraska it occurs in a somewhat similar situation, being found on the rocky buttes where there is very little soil.

No one about Lakeside, so far as I could learn, knows anything about the time the plant was introduced. The only reply to my question as to how long the plant had been there was that it had been noticed as long as the speaker had lived there. I have found it nowhere in the region except about Lakeside. The Lake Shore Railroad is about ten miles south of the place and a branch road now runs up. But the latter has

only existed a few years, being constructed long after the plant was present. Just how it made the thousand-mile journey eastward may never be known. But, nevertheless, the beautiful little waif is with us, and forms a very welcome addition to our Ohio flora. It has received the local name of Lakeside Daisy.

If this plant could be successfully cultivated it would make a valuable addition to our list of spring bloomers. The bright yellow blossoms in compact masses, coming so early in the season as they do, would supply a place now vacant.

Notes on the Plum Curculio.

THIS insect is still one of the most serious of our orchard pests. It attacks not only plums, but apples, pears, quinces, peaches and cherries, and disfigures where it does not destroy. Experiments looking to the destruction of this pest have been and are still made in some of the western states, and a good measure of success has attended them. In spraying for the codling moth a large number of the beetles are killed and the fruit is largely protected. Quite early in the season of 1890 I noted, in collecting on the June-berry (*Amelanchier Canadensis*), that many of the half-grown berries had the peculiar crescent mark indicating Curculio. A little beating about gave me a number of specimens of the mature beetle, so that the true culprit was not in doubt. The berries were, many of them, infested by a coleopterous larva, which I did not succeed in bringing to maturity, but which was not this Curculio. I have no real doubt, however, that the pest does breed in the June-berry if its more usual food-supply is scant. I had noticed in previous years that many mature apples showed scars of Curculio crescents, and sometimes even traces of a short gallery, evidently made by a young larva. It has been known that Curculio acts differently in different kinds of fruit, and that while it caused plums to drop, it did not have that effect on apples.

Based on these observations I made a few experiments this past season. I gathered on one day a lot of punctured plums and apples from the ground beneath the trees and placed these in separate jars on moist soil. I gathered from the branches of Apple-trees a number of apples showing many punctures, taking one or two out of a cluster and marking the branches. These plucked apples were separated into two lots—one placed on moist soil and one placed in a dry jar and kept changed as to position so as to prevent rotting. Another lot of apples, further advanced and showing only punctures apparently some days old, was plucked and placed on moist soil.

The apples and plums picked from the ground and placed on moist soil developed all, or nearly all, the larvæ. I believe there could not have been a difference of ten per cent. between punctures and mature larvæ. In some small apples as many as nine full grown larvæ developed! The apples plucked from the tree and placed on moist soil also developed a very large proportion of the mature larvæ. Those placed in the dry jar withered and did not rot, and did not mature a single larva! A fair proportion hatched, but as there was no decay the larva perished.

Of the more advanced apples with older crescents, placed on moist soil, a fair proportion hatched and came to maturity. While the larvæ were developing in my breeding-jars I made periodical examination of my marked branches, picking apples and cutting down on the Curculio crescents. In most cases the eggs never hatched; in some few instances the young larva did make its appearance, only to succumb before it had penetrated very far into the fruit. All the fruit examined which did not drop had not matured a single Curculio larva. It seems to prove that the larva needs a decaying substance to feed upon, and the matter is important in this wise: If all the dropped fruit in an Apple (probably also Pear and Quince) orchard is regularly picked up and destroyed, it would prevent the maturing of any larvæ in such orchards, and, by lessening the number of beetles, would of course lessen next year's damage. The obvious application is to the point so often urged by entomologists—keep the orchards clear of fallen fruit, and begin just as soon as the fruit begins to fall. By far the greatest amount of Curculio injury results from insects bred right at home, and this is especially true in the case of isolated orchards.

The simple and uncombined landscape, if wrought out with due attention to the ideal beauty of the features it includes, will always be most powerful in its appeal to the heart.—*Ruskin*.

New or Little Known Plants.

Solidago speciosa.

NO figure, it appears, has been published before of this handsome Golden-Rod, which is one of the most distinct and best marked of the numerous species which inhabit North America, and which, with the Asters, form the characteristic and the most striking feature of our autumnal flora. *Solidago speciosa* (see page 561) is a stout, smooth plant, with tall stems four to six feet high, and ample, ovate or oval, slightly serrate leaves; those on the lower part of the stem are contracted into long, broad petioles, while those higher up are short-stalked, or nearly sessile, and narrower, or oblong-lanceolate. The heads of bright, canary-colored flowers are crowded in erect racemes, forming a narrow, pyramidal panicle five or six inches long and one and a half or two inches broad.

Solidago speciosa is scattered from Canada and eastern New England to Minnesota, Arkansas and the mountains of North Carolina. It inhabits the borders of woods and copses in rich, rather moist soil. It is not a very common plant, and in New England it is one of the rarest of the Golden-Rods. Our illustration is made from a wild plant collected by Mr. Faxon in Newton, Massachusetts.

Foreign Correspondence.

Berlin Letter.

NOT long ago a meeting of German forest-officers was held at Cassel, and one of the subjects discussed was the naturalization of foreign forest-trees in Germany. Some foresters have been opposed to the introduction of exotic trees, while others have urged that tests should be made to determine whether the acclimatization of certain species would not be possible and profitable. These tests have been insisted upon because it is only by experiments that any true idea of the value of foreign trees for us can be obtained. The study of their growth in their native countries has little value for us because a profitable growth is the product of so many influences which differ widely from those surrounding them at home. After some less important tests made by the possessors of private forests in the year 1882 there was founded under the direction of the Government stations for various trials of this sort in all the German states. In the kingdom of Prussia alone there have been paid out in these eight years \$80,000 and nearly 1,500 acres have been planted with foreign trees. The delegates from Bavaria and Brunswick gave the results of similar experiments from their countries, which were generally successful.

The exotic trees tested may be arranged in three groups, as follows: 1. Those whose success has been demonstrated, including the Douglas Fir, the Tideland Spruce (*Picea Sitchensis*), Lawson's Cypress, Red Cedar (*Thuja gigantea*), Black Walnut, Shellbark, Mocker-Nut and Bitter-Nut Hickories and the Red Oak. 2. Those which excel German trees only in certain districts, including the Pitch Pine, the Red Cedar (*Juniperus Virginiana*), Nordmann's Fir, Sugar Maple and Black Birch. 3. Such as do not grow or are not worth cultivating, as *Pinus Jeffreyi*, *Pinus ponderosa*, Red Ash, White Maple, the California Maple, the Pig-Nut Hickory and the Big Shellbark (*Hicoria sulcata*). Allow me to add to this that there are some varieties of Douglas Fir which will not grow here at all, some which suffer from low temperature, and others which are among the best coniferous trees we have. The same is true of Lawson's Cypress. In the winter of 1879 and 1880 we had a good stock of this tree at Proskau, in upper Silesia, each plant being a fine specimen six feet high. In February snow fell to the depth of three feet and the temperature sank to thirty-two degrees below zero Fahr. Every tree died down to the snow line, but all started well the following year from the part below the snow, which had remained healthy. In the same winter the Pin Oaks did well. I cannot understand why such an unfavorable opinion of the Black Birch was expressed, as it reaches a large size in St. Petersburg, and it does not suffer in a temperature many degrees below zero. Seedlings of the White Maple, too, I have found to resist a cold of the same intensity.

The fruit-growing industry of northern Germany is beset with many difficulties, the chief of them now being the high railway rates, which prevent the transportation of fruit to

Fig. 74.—*Solidago speciosa*.—See page 560.

southern Germany, where large quantities are used. This market is supplied from Austria because of lower prices, although the north German fruits are of better quality, and would be used if the railway rates were cheaper. Horticulture, too, is suffering much from natural and artificial causes. The countries which border Germany have high duties on imports,

while Germany has none; therefore the German nurserymen are prohibited from exporting, but the neighboring countries can send in cut flowers, vegetables and pot-plants at such low rates that it is impossible to compete with them. The horticulturists are urging upon the Reichstag the establishment of duties, but meanwhile the Berlin Horticultural Society has been

doing what it could to help by establishing horticultural experiment stations, out of its own funds, at which investigations are to be made to ascertain if there are feasible methods of raising plants and vegetables in a shorter time or at a lower price by the use of artificial manures. It is to be hoped that the state will create a larger station with similar objects. A greater disaster was last summer brought upon the nurseries in Saxony by the flood of the River Elbe, which overwhelmed many of them. All the plants in the greenhouses and hot-houses, with the exception of *Rhapis flabelliformis*, were lost. The distress has been so great that collections are now taken up throughout the whole empire for the sufferers. Money as well as plants and seeds and cuttings are welcomed. If any German nurseryman in America should read these lines he might help his brethren in the old world by sending money or cuttings to the Vorstand des Verbandes deutscher Handels gärtner at Leipzig. "Die noth ist furchtbar."

It may be of interest to American women to know that more than a year ago a school of gardening for women was established here. It has a three years' course, during which time the general art of gardening is taught theoretically and practically. Opportunity is also afforded for training in any special department of gardening, and a section devoted to landscape-gardening has just been started. The classes have already won some medals at different exhibitions. There is also a ladies' society to encourage plant-growing at home. Its members are wealthy, and they offer gold and silver medals for pot-plants.

Of the floral novelties grown this year the most important is a Begonia which seems to be a cross between the variety Diadema and some other form of *B. Rex*.

Cultural Department.

Early Chrysanthemums.

THERE seems to be an increasing interest in the effort to secure early blooming large-flowered Chrysanthemums. No doubt if our borders could be filled from late August or early September till hard frosts with satisfactory specimens of these free-blooming, showy plants it would be a great gain. The prospect of success in that direction seems to me slight; and judging from the progress made, and from the nature of the species, it does not seem that good early Chrysanthemums in the open air will ever be abundant in this latitude. The Desgranges (Madame C. Desgranges, G. Wermig and Mrs. Hawkins) are the best of the early large flowering varieties. Madame Desgranges has been cultivated for some years, is of undoubted merit and at present is the most favorable example which can be named of the race. This variety with me is a fair grower, rather dwarf in habit and with a decided tendency to rust. Of course, with care, it may be kept in good condition as to foliage. It is a simple matter to bring it into full bloom in late August or early September, and well grown flowers are very satisfactory if protected. The difficulty is just here—good, deep, full Chrysanthemum-flowers are very quickly ruined by rains or excessive moisture, and need overhead cover; any such cover will make them so delicate that they will be quickly scorched by the torrid sun which often prevails at that season, and usually an early frost will sear plants before the flowers wane if unprotected. On a border under the south side of the house Chrysanthemums are at this writing (November 15th) still in full bloom entirely untouched by frost—we have had five degrees once—and in such a position it might seem that early kinds could be successfully grown. Possibly the culture might be a success if such weather could be depended on, but this is the first time in a decade when such conditions have prevailed, and one chance in ten is scarcely satisfactory. With us killing frosts may be expected any time after September 20th, and after that date protection may be required at any time, though usually plants are safe till October 15th. Now, with the drawbacks as stated, it does not seem worth while to grow a race of flowers which at the best are of inferior merit to the later kinds at the necessary expense of time and trouble, when the space can be used for fine mid-season or late ones.

In the early season, also, Asters are in season, and likely to be more satisfactory. The early Chrysanthemum is not for me, except for a trial of new varieties as a matter of interest, and I am well content to wait till early October, when, with the keen frosty air, one can enjoy the beautiful blooms of Madame Lacroix, Lady Selborne, William Holmes, William Cobbett, M. E. Nichols and others. The Chrysanthemum is surely a cold weather flower, and naturally at its best at that time. To use a homely analogy, it is somewhat like Celery. The early

Chrysanthemum is no more like the later ones than the stringy, rank celery of August is like the crisp, nutty celery of late fall. This quality seems inherent in the nature of the plant, and probably can be little changed by cultivation or selection.

Where an effort is made to have successive displays of good showy flowers it would seem that large breadths of Japanese Anemones are more desirable and satisfactory flowers in the same season for such a purpose than the early Chrysanthemums. They are among the choicest and handsomest of hardy plants and the very best of hard weather flowers, preserving their purity and beauty through the severest storms of wind and rain and not affected by an ordinary frost.

Elizabeth, N. J.

G.

Notes from the Harvard Botanic Garden.

CENTAUREA AMERICANA.—This plant, and its variety, *Hallii*, are both well worth trying in the garden. They are annuals, natives of the southern states from Arkansas to the border of Mexico. The typical form has a smooth, occasionally branching, stem, which averages about four feet in height under cultivation here. In its natural state it is sometimes six feet high. The alternate, sessile leaves are oblong-lanceolate, and gradually diminish in size until the smallest at the summit measure about one and a half inches in length. The terminal flower-heads measure four inches across when fully expanded, the exterior florets being of a rich rose color, and those of the centre somewhat paler. The flower is handsome, and remains for a considerable time in perfection on the plant or in water. The variety differs from the type in that its growth is slightly more delicate, the leaves approaching ovate-lanceolate, and its flowers are deep purple. Sow the seeds under cover early in spring, in a temperature not lower than fifty degrees. Transplant, when large enough, in a frame where growing heat can be maintained for a time; harden off the seedlings as the weather grows warmer, and finally remove them to good soil in a sunny part of the open garden in late spring. The flowers will appear early in August, and continue to appear until the plants are cut down by frost.

CHRYSANTHEMUM ULIGINOSUM.—This plant, the *Pyrethrum uliginosum* of Willdenow, affords a grateful mass of showy flowers in September and October, and its habit of growth makes it useful in the garden at a time of year when good flowering plants are scarce. It is a native of Hungary and quite hardy in Massachusetts. The stems are from four to five feet high, thickly furnished with sessile, lanceolate, serrate leaves, and branched at the top. A single stem produces from nine to a dozen branches, which in their turn bear, according to strength, from one to four Daisy-like flowers three inches across, and pure white, with bright yellow disc. It is a most useful plant for the back lines of an herbaceous border, and strong clumps dotted about among dwarf shrubs have a telling effect. A soil of medium quality and moderately heavy is the most suitable, for, like most of its kindred, it is a voracious feeder. It is of importance, more for the quantity and quality of the flowers than for the appearance of the plants, that as many as possible of the leaves be kept in healthy condition until the flowers are past their best. This is a task of some difficulty in very dry seasons, because the lower leaves are much inclined to wither and fall in time of drought. A light mulching and occasional supplies of water will be beneficial in such extreme cases.

CROCUS SPECIOSUS.—The showy flowers of this lovely species have a strange look now as they peep above the earth just as the fall frosts come, and very bravely do they withstand the alternation of heat by day and cold by night up to about the middle of October. They are almost three inches across when open in the sun, and it is then that they are most charming. The soft lilac of the segments is profusely marked with diverging and intersecting lines of deep purple, the colors being most distinct and beautiful in the interior. The showy yellow anthers and stigmas of a deeper shade afford a desirable variety of color. The leaves, differing but little from those of vernal Crocuses, appear only in spring. In its native state, according to Baker, the plant is distributed from north Persia and the Caucasus, through the Crimea, to Hungary and Transylvania. It is the most desirable and reliable autumn-flowering species for this climate. Plant the corms in any good garden soil and in a position where they will not be disturbed. They do best and bloom most freely when left to themselves, merely keeping their quarters clear of weeds and covering with soil any corm that seeks the light.

DIANTHUS PLUMARIUS SEMPERFLORENS.—This plant is said to be the result of crossing *D. plumarius* with a Carnation; but whatever its origin, it is a most desirable one. It has proved hardy here, having stood out all last winter with only a slight covering of protecting material. The growth is dense,

but straggling rather than compact, a habit rendering it an admirable subject for the rock-garden. The flowers vary from light to dark rose, with darker band in the centre. They are pleasantly fragrant and sometimes measure almost two inches across. They are flat in general, and invariably single, with the edges irregularly toothed. The mass of bright glaucous foliage forms an appropriate ground for their more brilliant colors. But the best quality of the plant is the freedom and persistence with which the flowers are produced. Since early summer, through storm and drought, up to this first week of November—and we have had several frosty nights—flowers might have been picked any day from the same plants. They are of a deeper color and smaller, but still beautiful and fragrant in this colder weather. Any of the forms may be perpetuated by propagating from cuttings, and, subject to the slight variation already mentioned, the plant may be readily raised from seed. Our plants were raised from seeds for-

TRICYRTIS HIRTA.—This is an interesting Liliaceous plant, commonly called the Toad Lily (in reference to the profusely spotted flowers), and introduced from Japan in 1863. In this locality it is perfectly hardy, with simple or distichously branched hirsute stems from three to four feet high; alternate, stem-clasping, ovate, deeply veined, hirsute leaves, and shortly paniculate axillary inflorescence. The bell-shaped flowers, an inch or more across, are borne on pedicels about an inch long, the divisions being white densely spotted with purple on the upper surface. The conspicuous filaments are similarly marked. The flowers are extremely pretty at short range, produced in large numbers during October and November, and they last until destroyed by severe frost. Those at the top of the stem are the first to develop, and they open downward in succession. The plant likes partial shade and good soil, and will extend rapidly if left to its own way under these provisions. It is most effective in masses of a dozen or more,

A Michigan Forest of the Present Day.—See page 559.

warded by Mr. W. Thompson, of Ipswich, England, some two years ago. It is a new plant to this country, and, considering the severity of the climate, one with a most promising future.

SOLIDAGO DRUMMONDII.—This species is the last of the Golden-rods to flower. It is a highly ornamental plant, commencing to bloom early in October, and still in flower, though fading somewhat early in November. The stems are rather slender, three to four feet long, and from the weight of the flowers frequently prostrate if not secured by staking. The dark green of the ovate, serrate leaves contrasts well with the vivid yellow of the abundant flowers. Planted freely on a steep bank, that from its situation will not be allowed to get very dry in summer, and allowed to grow in its own way, without tie or prop, the effect is strikingly beautiful. The flowering-stems impart unmatched elegance to floral decorations. The plant likes partial shade and good, retentive soil. It is found from Illinois and Missouri to Louisiana.

and when these masses attain large dimensions, as they will in a few years, the roots may be separated late in autumn for fresh plantations. It is possible to propagate more closely by removing the offsets yearly.

Cambridge, Mass.

M. Barker.

Notes on Shrubs.

IT usually happens in this latitude that at least three-fourths of the deciduous trees and shrubs lose their leaves by the first week of November. Sometimes, however, there is considerable variability in persistence of foliage even among plants of the same species, although, as a rule, all of a kind may be fairly judged by the behavior of two or three healthy individuals growing under normal conditions.

After several severe frosts the best foliage of all the species of *Clematis* in the collection is that borne by the Japanese *Clematis paniculata*, which still appears as fresh and green as in

midsummer. *C. Vitalba* is in almost equally fine condition, and *C. Viticella* also maintains a fairly fresh look. The leaves of nearly all the other species have either ripened and fallen or they have been totally or partially destroyed or blackened by frost. None of the species here assume bright autumn colors, but the leaves of a few occasionally have a purplish aspect.

There is no hardy dwarf shrub which surpasses the Yellow-root (*Zanthorhiza apiifolia*) in brilliancy of late autumn foliage, none of which has fallen at the end of the first week of November. The leaves at this time are brightscarlet and orange in color, and this autumnal glow constitutes the chief value of this plant for ornamental planting. It is perfectly hardy, and as it only grows from one to two feet high, and spreads from underground shoots, it is admirably adapted for planting as an under-shrub in open places or at the edges of the shrubbery.

The species of Strawberry-bush (*Calycanthus*) generally lose their leaves by the end of October, and although they sometimes become yellowish they usually fall without showing much or any autumnal color. Considering the profusion of flowers which it bears, it is surprising how seldom such a hardy species as *C. levigatus* bears fruit. Very few of the people who are familiar with the strawberry-scented flowers know the rough, stout pods or hips, several inches in length, and filled with large brown seeds. Occasionally a few hips are produced on plants in this region, and they are so formed that they may remain suspended from the branches for a year or more and retain the seeds in a perfectly dry condition and unaffected by the weather. It would be interesting to know the manner of the dispersion of these seeds in the native habitat of the plant in the Alleghanies, and whether anything more than the disintegration of the hips and consequent liberation of the seeds is provided for. If the seeds only escape by the decay of the hips they must retain their vitality for a considerable time.

Among the Barberries the only one that is perfectly leafless by the 1st of November is the Asiatic plant known as *Berberis Amurensis*, but which is often accounted only a geographical variation or form of the ubiquitous *B. vulgaris*. Its stiff, unbending, upright habit, as well as some other minor differences, render it easily distinguishable from the last named and all other kinds. Its upright habit is imitated by another Asiatic species, *B. Sieboldii*, which retains its crimson and orange foliage a little while longer. In the common Barberry persistence and coloration of foliage in autumn depend very much on situation. As a rule, the colors are not very bright, and a good portion of the leaves have fallen by the first week in November; sometimes, however, they maintain a leafy appearance until late in the month. All other species still retain more or less of their foliage; but, except some half hardy evergreen species, none of them hold their leaves so perfectly and with relatively so little change as a plant received from various botanic gardens as *B. Sinensis*, which is still bright green, although showing a little orange and yellow. The beautiful fruited *B. Thunbergii* has lost most of its leaves, which have been conspicuous during several weeks for their bright orange and scarlet coloring.

The fruit of *B. Sinensis* is very similar to that of the common Barberry, being very juicy and pulpy, and also shriveling and losing much of its brightness of color after several freezings. It is also of a much darker red color than the berries of *B. Thunbergii*, which are usually dry and tasteless, and remain bright, fresh-looking, plump and unshriveled throughout the winter. *B. Sinensis* is rather a plant of more slender and graceful habit than the common Barberry, and it differs strikingly from the compact and bushy form of *B. Thunbergii*, which is certainly much more desirable and valuable for strictly ornamental purposes. It is altogether probable that branches of the bright scarlet fruit of the latter will come to be much used as a substitute for Holly in Christmas and other winter decorations. The spiny character of the stems is against such use, but the tenacious clinging of the fruit to the branches which the species possesses is a very desirable quality. As with many other plants, the seed of this Barberry germinates more readily and quickly after being subjected to hard frosts.

Ilex decidua continues to hold all of its leaves in a bright and fresh condition, while those of *I. monticola* have all fallen, as has the foliage of *I. laevigata*, which turns to a clear yellow before it drops. The Black Alder (*I. verticillata*) does not assume any bright autumn color, and now more than half of its partly brown leaves have already fallen, leaving the bright red fruit more conspicuous than ever. There is a bright light yellow fruited form of this species which is well worth planting with the type to give variety and show contrast of colors.

The Japanese *Ilex Sieboldii* is another hardy species which is early deciduous, the leaves assuming a deep reddish purple hue before they fall. The fruit has not yet been produced in abundance here. Although small, the berries are of a deep, dark red color; and the plant promises to be of some ornamental value.

Quality in Apples.

"THE less definition, the more dispute." This statement must be regarded as an axiom of science; but when we set beside it the old proverb, "There is no disputing about tastes," how shall we approach the subject of this article? This approach must be made mainly from the practical, even the commercial, point of view. The nation's supply of fruit must be produced by its commercial fruit-growers; and as the great bulk of our people are in moderate circumstances, they must be supplied with fruit not too costly for their means. The choicest fruit is not, cannot be, for the multitude, because it cannot be produced in sufficient abundance, nor at a popular price.

Nevertheless, an abundance of fruit can be produced which has qualities good enough to insure a very large demand; and it is important that growers who mean to supply this demand should learn as much as possible about the marketable value of the different varieties.

Apples do not differ from other fruits in regard to this matter of quality, except in this, that very few fruits preserve their quality so long as our late-keeping apples. The buyer gets this class of apples nearer to its best than any other fresh fruit prominent in commerce. Most buyers of apples are in a way judges of the quality of the fruit, and within the limit of their pomological education they may be very good judges. But it is certainly a fact that our most popular apples are generally not the best for eating uncooked. Neither are our best dessert apples always the best for cooking. Nor is the public taste agreed upon a standard of excellence in regard to dessert apples. Beauty, as a confusing element, is to be considered. Handsome apples, even of quite inferior dessert quality, find a ready sale.

There is no apple so good that everybody likes it. In Canada and New England the Fameuse (Snow Apple) ranks with the first in popularity and price, and eminent pomologists allow it place among the first as a dessert fruit. Yet a pomologist in high station writes me that "the Montreal people may consider Fameuse a choice dessert apple, but it is certainly not so considered in the true apple-growing section." Yet Downing says, "It is an excellent apple"; Thomas says, "Much admired as a table fruit for its pleasant and refreshing flavor"; and not to quote further, the fact that it leads in favor for its season in so fastidious a market as that of Boston ought to have considerable weight in estimating its position. Esopus Spitzenburgh is frequently allotted the first position among later apples, but with all its high, rich flavor, its flesh is never soft or mellow, and some will grant it only the first place as a pie and sauce apple. The Newtown Pippin has long led as an export apple of dessert quality, yet many do not like it. Peck's Pleasant has been awarded the very highest position by connoisseurs, yet it has never attained wide popularity. Rhode Island Greening is a favorite of many pomologists, and is extremely popular; but it is only when yellow-fleshed that its merit is conspicuous. A green-fleshed Greening is always inferior. Yellow Bellflower is, when well grown, a superior apple, but otherwise is of little value. The same is to be said of the King of Tompkins, and indeed of very many sorts. Almost every apple-growing section has its apples of local celebrity, little known or esteemed elsewhere.

For the general market, long experience shows that there must be, with the keeping varieties at least, a union of both cooking and dessert quality to ensure general salability. Much more of this fruit is eaten cooked than uncooked, and an apple that will not make good pies stands at a marked disadvantage in the market. It must not only have a good flavor which will stand fire, but it must cook quickly and thoroughly; and an apple that will not answer this requirement can never be popular. The King, the Baldwin and the Greening are leading apples in market, because, along with ease of production, they possess this double utility. Cooking quality, therefore, is of as much importance as dessert quality. In determining the value of the great commercial apples it may, indeed, be said to lead.

The finest dessert apples are sometimes good culinary fruit, but most of them lose part or all of their excellence under the test of fire. So far, they may be regarded as inferior in the fruit market. Their place is on the fancy fruiterer's counter,

to be sold for exactly what they are—table fruit. Some of the very best, notably Pomme Grise, are almost excluded for lack of beauty and size. On the other hand, for apples for the street stands, where immense quantities are sold, beauty is of the first importance, and this, joined with moderate softness of flesh, is of much more consequence than high flavor. From one end of the Mississippi Valley to the other Ben Davis is the omnipresent apple; and much as its quality is denounced in the meetings of our pomological societies, its very denouncers plant it by the quarter section because it sells.

Fruit-growers who have been brought up on Ben Davis, and who have been forced to grow it against their will, are to be pardoned for some violence of feeling against apples of inferior quality; and I seem to notice that it is they who are the severest critics of the apples of north-eastern Europe. They will admit their beauty, as well as the hardiness and productiveness of the trees; but because among them merits equal to those of the Greening and the King have not yet been recognized, their patience will not hold out until time elapses for their careful trial and estimation. They rush into denunciation as a sort of relief, and kick them as a man kicks the cat when he is angry with his wife.

I do not think they are wise in this. Let patience have her perfect work. Of these apples of eastern Europe upward of 250 varieties have been imported and are now under trial. It is an immense task, and nothing but preliminary and tentative reports can yet be made by any one. I have been at work upon them for twenty years, and yet I am unacquainted with the qualities of four-fifths of them. In one-fifth I have found three sorts that I am planting for profit: one, the Yellow Transparent, for summer; another, Prolific Sweeting, for fall, and a third, Longfield, for early winter. A fourth, Bogdanoff, is plainly a keeper, but only this year have I obtained enough of these to give them a preliminary testing as to season and quality. Professor Budd, of Iowa, has the whole list under trial in the college grounds at Ames. From him I have lately received specimens of six large and handsome winter varieties which I am also subjecting to test as above. The fact is now established that all these apples are not early kinds. I trust that patience will be exercised in awaiting the careful trial, vitally necessary in the interest of the cold north, of these hardy, beautiful and productive fruits. They will not hurt anybody, and no one is going to gain any credit that he will not richly earn in the long, laborious and careful efforts needed to assign these fruits to their proper position in our pomological records.

Newport, Vt.

T. H. Hoskins.

Nematodes Again.

LAST year I made an examination of Coleus leaves to ascertain the cause of the serious blotching of the foliage, but nothing in the nature of a Fungus could be found. The knowledge of Nematodes obtained during the past year suggested a re-examination of the Coleus foliage for microscopic eel-worms. Upon thoroughly dissecting the first leaf-blotch a number of the worms were brought to light, and their presence was constant throughout the large number of leaves examined. Without attempting to identify the species, which, so far as general appearance goes, closely resembles the one on the Violet, Spinach and Chrysanthemum—namely, *Heterodermis radicola*—the fact remains, that the worms are there and seem to be the only observed cause of the blackening of the Coleus leaves and their premature falling. The light colored leaves are much more noticeably blotched than the dark red ones, but all sorts seem to be equally the prey of the worms.

Spots or blotches similar to those upon the Coleus were recently found upon all the leaves of a sickly specimen of *Lantana* growing out-of-doors. Upon examination for some *Cercospora*—for the spots appeared to have a mould upon them—it was quickly found that here again were the Nematodes. Every spot, large or small, contained many worms, and they were active in the soft parts of the leaf between the upper and lower epiderms. These spots, as those of the Coleus, were bounded quite regularly by the veinlets of the infested leaves, and it is probable that the denser substance of the veins may serve as a check to the spread of the worms throughout the leaf. The roots of the affected Coleus plants contain many galls, and in these the worms may be found in all stages of development. It is hoped that some helminthologist may find this branch of his subject—namely, Nematodes in leaves—of sufficient importance to warrant a study of it. There are many interesting questions that arise concerning the worms beside the extremely practical one that always

comes up from every gardener—namely, what shall be done for the trouble? Suspicion of Nematodes may well be aroused whenever leaves are brown in patches and otherwise green when no insect or Fungus can be found.

Rutgers College.

Byron D. Halsted.

The White-Flowered Perennial Pea.—English periodicals contain considerable information recently regarding this plant (*Lathyrus latifolius albus*) and its propagation by seed. Some writers assert that a large proportion of the seedlings come true—that is, with pure white flowers—from seed. Raising this Everlasting Pea from seed, however, means growing the plants on until the second year to test them as to their color, and this, no doubt, accounts for the high prices demanded in Europe for the plant. But it is surprising that one should go to the trouble of raising seedlings of doubtful color when the genuine plant may be easily propagated by means of cuttings. We have usually cut off the whole of the tops of the plants in fall, using two joints to each cutting, and have invariably found that seventy-five per cent. will root readily, grow rapidly and flower the ensuing summer. After the tops have been cut off, if desired, the root may be lifted and placed in a deep box in a greenhouse, where an abundance of young shoots will appear, and these, if taken off while short and stocky, also root freely. When this plant becomes better known and cheaper we may hope to see it frequently used as a screen plant, for these perennial Peas need support just as Sweet Peas do. They are out of place in a border, for they spread rapidly among other things, and the rain bespatters the flowers with dirt, marring their purity. But if the plant has a chance to climb, a little assistance at starting and good, deep rich soil, the result will be a revelation. One thing to be remembered is, that these Peas, in common with most leguminous plants, transplant badly, and an old plant to start with is not half as good as a young one. It takes a good deal of digging to lift an established root of this Pea, and when replanted the old roots need twelve months in which to become re-established.

South Lancaster, Mass.

E. O. O.

Young Fruit-trees.—We have never found a better way to judge of the bearing of young fruit-trees, and to decide whether they are bearing too little or too much, than to observe the length of the annual shoots. The treatment is then to be given in accordance with the result of this examination. If the growth is slow, mellow culture or fertilizers will be necessary. If, as generally happens, slow growers bear too much, thin out most or all the fruit when small, which will aid in giving the trees more vigor, and what little fruit there is will be worth more than the numerous small and scrubby specimens. Small growth and too much small fruit go together, and thrifty growth furnishes a few large and fine ones. If the annual shoots are not over a foot long in the early years of fruit-trees, more vigor must be given them. Nothing is better than top-dressing with barn manure late in autumn or early in winter.—J. J. Thomas, in *Country Gentleman*.

Correspondence.

Some Early Wild Flowers.

To the Editor of GARDEN AND FOREST:

Sir.—Although most persons think there are no flowers to be found in our New England woods or fields from the last of November to the first of April, they have been found in this neighborhood in every month in the year. For twenty months in succession, from April, 1879, to November, 1880, some wild plants were in flower near Boston. Colonel Higginson, in his delightful "Out-Door Papers," says: "The first wild flower of spring is like land after sea. The two which throughout the Northern Atlantic States divide this interest are *Epigaea repens* and *Hepatica triloba*." For many years I have thought they blossomed about the same time. The Mayflower does not grow in any quantity near Boston, so that I have not had the opportunity of watching it closely. But my favorite spot for *Hepatica*, in Middlesex Fells, is only six miles from Boston. When I first collected the flowers here I used to think myself fortunate if I found a good bunch of them on Fast Day. At that time a friend told me he had once found these plants blooming in February. After that, whenever I was near the place on a mild day in winter, I looked for them, and at last, on the 11th of January, 1874, I found several plants in flower, and one out of blossom, with only the involucre and seeds left, indicating that it blossomed in December perhaps. I found it in flower March 21st, 1878; March 7th, 1880; November 30th, 1881; November 30th and December 31st, 1884;

January 2d, 1885. On November 30th, 1886, I found a single plant in bud, and marked the place by breaking the top of a bush by which it grew, and on December 9th, after three or four cold days with the thermometer at about ten degrees, after a three days' snow storm, I found it in blossom under more than a foot of snow.

Since then, having removed to Malden, I have had a better opportunity to watch the plants, and have found them in flower eight months in succession. In 1889, October 20th, November 12th, December 8th; in 1890, January 2d, February 13th, March 30th, April 6th and 20th, May 4th and 7th. When I found it in flower in October I thought it must be earlier than the *Epigæa*, but a friend to whom I sent one of the flowers, in acknowledging the receipt of it, writes: "My sister found on the same day in early October the *Epigæa* and fringed *Gentian*," so that I am still in doubt, as one of the plants which I found on the 20th must have been in flower some days, the petals having fallen from all the flowers but one.

Since writing the above I have learned that the *Epigæa* was found in flower near Williamstown about the 19th of September, 1878.

Another of our early-flowering plants which has generally been overlooked is the *Ranunculus fascicularis*. This was in blossom in Middlesex Falls, November 10th and 12th and December 8th, 1889.

Malden, Mass.

E. H. Hitchings.

Recent Publications.

Hooker's Icones Plantarum, volume x., part ii., September, 1890.

This issue of *Hooker's Icones* is principally devoted to figures of new Chinese plants, and is of unusual interest. Several of the plants here first made known are important trees; some represent new generic types, while from the cultural point of view many of them are of special interest to us, as it is more than probable that the plants of western China will flourish in the middle and perhaps northern states as well as in many parts of central Europe. So far as hardy plants are concerned, west central China is the only great field of enterprise which is left uncultured, and the collector who follows in Dr. Henry's footsteps, with the view of introducing into cultivation the plants of the mountain region of western China, will reap a rich reward and perform a great service to horticulture.

A mere enumeration of a few of the plants here figured will serve to give an idea of the richness of this Chinese flora and of the treasures which await the enterprising collector: *Tilia Tuan* (t. 1926) is a tree described as forty feet high, with ample membranaceous leaves, covered on the lower surface with white stellate tomentum. The bark is used in making shoes. *Tilia Henryana* (t. 1927) is a tree described as thirty feet high, with leaves smaller than those of the last, and covered on the lower surface with fulvous pubescence. There is a third new Linden, *T. Oliverii*, from the same region where the Japanese *T. Miqueliana*, already introduced into cultivation from Japan, was also detected by Dr. Henry.

Professor Oliver proposes a new genus, *Tapiscia*, for a tree which he places provisionally in *Sapindaceæ* on account of the copious albumen of the seed, the presence of conspicuous stipules, and the resemblance of the leaves to those of *Euschaphis* and some other *Staphyleæ*, although the leaves are alternate and the ovary is unilocular and uniovulate. *Tapiscia Sinensis* (t. 1928), the only species, is a tree with leaves eight to fifteen inches long, with three to five leaflets, sessile panicles of small, regular, hermaphrodite flowers, and subglobose, dry, indehiscent fruit. The generic name is an anagram of *Pistacia*, which the dried specimens of this remarkable tree suggested to Professor Oliver.

Fraxinus platypoda (t. 1929), with curiously dilated petioles, is a new Ash described as twenty feet high. *Fraxinus retusa*, var. *Henryana* (t. 1930), is a form with broader leaflets of a plant previously known from Hong-Kong.

There is a new plant of the Witch-Hazel family, *Sycopsis Sinensis* (t. 1931), a genus previously represented by a single species collected many years ago in Khasia. *Cephalotaxus Griffithii* (t. 1933), a species previously known from upper Asam and Munnipore, is here first figured from Mr. Faber's Chinese specimens.

Schizophragma, a genus previously represented by a single Japanese species now a familiar object in gardens, is enriched by a second species discovered on Mount Omei by Mr. Faber, for which Mr. Oliver proposes the name of *Schizophragma integrifolia* (t. 1934). It is distinguished from the Japanese plant by its more coriaceous leaves, which are not cordate at the base, and by the narrower petaloid calyx-limb of the abortive ray-flowers, these being represented by the more conspicuous

rudiment. A curious form of *Fagus sylvatica*, the old world Beech-tree, characterized by very long leaf-stalks, is distinguished as var. *longipes* (t. 1936). In *Menispermaceæ* there is a new *Cyclea*, *C. racemosa* (t. 1938). *Populus lasiocarpa* (t. 1943), described as a good timber-tree, is common on the mountains at elevations of from four to six thousand feet.

Two new Blackberries are described, *Rubus malifolius* (t. 1943) and *R. simplex* (t. 1948), and a remarkably anomalous plant, for which a new genus of uncertain relationship, *Eucomia*, is proposed. The fruit and general aspect of the specimens suggested *Ulmaceæ* to Professor Oliver, but no trace of perianth could be found in the flowers dissected from the small axillary buds. The leaves are destitute of stipules, and "in the cell of the fruit, which survives and includes the solitary seed, there is always present a collateral or nearly collateral pendulous abortive second ovule." This remarkable tree, *Eucomia ulmoides* (t. 1950), which is cultivated in the districts of Changyang and Patung, was not seen by Dr. Henry in a wild state. It is of considerable commercial importance, being highly esteemed by the Chinese in their materia medica; and "the most singular feature about the plant is the extraordinary abundance of an elastic gum in all the younger tissues, excepting perhaps the wood proper—in the bark (in the usual sense of the word), the leaves, and petioles and pericarp; any of these snapped across and the parts drawn asunder exhibit the silvery sheen of innumerable threads of this gum." The bark, according to Dr. Henry's notes, "is the most valued medicine of the Chinese, selling at from four to eight shillings a pound. The tree is planted from the seeds and is cut down in the third to the sixth Chinese month and stripped of its bark. During the last twenty years the production seems to be diminishing from Cheshuan, from which it chiefly comes, and the price has increased four or five fold."

A number of interesting and a few handsome Chinese herbaceous plants are figured in this issue, which contains also several new plants, with one new genus, *Tisonia*, in *Boraginææ*, from South Africa.

Exhibitions.

The Boston Chrysanthemum Show.

THE complaint has been general that this has been a trying year for Chrysanthemums, and yet Boston never before saw such a magnificent array of well-grown plants as those displayed at the annual exhibition last week, and the cut flowers, especially those grown by Mr. S. J. Colman, equaled the plants in quality. The collection of flowers in vases, shown by Galvin Brothers, but also grown by Mr. Colman, made a noteworthy feature of the exhibition, showing the high decorative value of these large Chrysanthemum flowers when properly arranged in large vases.

The prize collection of twenty named plants was exhibited by Mr. Walter Hunnewell, and contained the following varieties, all superb examples of the most intelligent cultivation: Minnie Miller, Hon. John Welch, General Latimer, Empress of Japan, Marvel, Needless, Sachem, Cullingfordii, William H. Lincoln, Diana, Echantresse, Neesima, Mr. John Laing, Norumbega, F. McFadden, Kioto, Fair Maid of Guernsey, Lilian B. Bird, Duchess and Robert Bottomley.

The prize for a specimen plant of a Japanese variety was also awarded to Mr. Hunnewell. The variety shown was Mrs. Alpheus Hardy, and, even without considering the acknowledged difficulty in growing this variety well, it was a splendid plant. It stood five feet high in a twelve-inch pot, and at the top measured five feet in diameter. The head was literally a mass of snowy bloom, and each flower was of fine size, form and substance. Other prizes for plants in pots were awarded to Mrs. Francis B. Hayes, Dr. H. P. Wolcott, Nathaniel T. Kidder, Dr. C. G. Weld and the Bussey Institute.

A rather pleasing feature in this department was the general collection of plants from the Bussey Institute. Having been allowed to grow pretty much as they pleased, and arranged here with faultless taste, they showed that untrained plants have for decorative work a utility and charm with which formal specimens cannot compete. Two varieties, *Source d'Or* and *Minetto*, were especially attractive in this group. The former is a Japanese variety, with flowers of deep orange yellow tinged with bronze; the latter a pompon, in which the flowers are of a soft amaranthine purple. In these a single stem had been allowed to run up for some distance, and then a head was formed in the way of a standard. The branches were not trained in any way, and the weight of the flowers caused them to droop gracefully in a cluster on one side, thus forming a very pleasing picture.

The special award of a silver medal to T. D. Hatfield, Mr. Hunnewell's gardener, was an appropriate recognition of his skill as a cultivator of *Chrysanthemums*. A similar medal, and one equally well merited, was awarded to S. J. Colman.

The seedlings were numerous, but few of them were of sufficient distinctness and value to supplant old favorites. The Society's silver medal for the best seedling of 1889 was won by Arthur H. Fewkes with a variety named Beacon. It was a large loose flower, with petals incurving slightly and pure white. In the same class Mr. S. J. Colman was second with Albert Henry, a very large flower (fully eight inches across), of the Edwin Molyneux style of petal, but only slightly incurved, and nodding instead of erect, thus showing the centre conspicuously. Mr. James Wheeler was third with Mrs. Joseph H. White, a large flower, with petals inclining to a horizontal position, broad, white-margined and deeply tipped with pink. The Appleton medal was awarded to Henry A. Gane for seedlings, and Mr. T. H. Spaulding's seedling, D. D. Farson, received honorable mention.

Mr. George B. Gill exhibited a sport from St. Patrick (Beethoven), with pale yellow petals slightly tipped with red. It was of good form, and sufficiently full and distinct to deserve perpetuation. The poor lasting qualities of the flowers of Mrs. Alpheus Hardy were well brought out during this exhibition. Even upon the plant they do not stand like many other well known white varieties.

A silver medal was awarded to Richard Gardner, gardener to Cornelius Vanderbilt, Newport, Rhode Island, for a new hybrid *Calanthe*. This plant is the result of crossing *C. Veitchii* and *C. vestita rubro-oculata*, the latter being the seed-bearing parent. The flowers are much larger than those of either parent, and of a much purer white color than those of the latter, with large pale rose blotch at the base of the lip.

Boston.

B.

The Autumn Exhibition in Philadelphia.

THE exhibition of *Chrysanthemums* in Philadelphia last week was admirable for the size and vigor of the plants, for the abundance and perfection of the cut blooms, and for the richness, variety and distinctness of the seedlings displayed. It was so well balanced throughout that no special department deserves praise which should not be accorded in equal measure to all the rest, and it is difficult to characterize the show or any part of it without the use of superlatives. The arrangement of the plants in the large hall was very effective. The long tables of Ferns, Palms and other plants with a luxuriance of foliage not only helped, to soften the glitter of the flowers, but the collections themselves were of rare merit. The plants exhibited by Thomas Long, gardener to A. J. Drexel, contained many rarities, which were attractive in themselves and arranged with rare skill. Among the choice plants in this collection were specimens of *Heliconia aurea striata*, *Aglaonema pictum*, *Spathiphyllum pictum*, *Dichorisandra musaica* and *Livistona Sinensis aurea*. Hardly less interesting was the table of Palms, Ferns, etc., of Charles D. Ball, Holmesburg, Pennsylvania, which contained nothing but plants taken directly out of the nursery stock. Among them there were no expensive rarities, but their vigor and health and tasteful grouping made them very effective. The collection of the same class of plants grown for ordinary purposes by Mr. H. A. Dreer was equally meritorious, and the assortment of decorative plants by William Joyce, gardener to Mrs. Baldwin, was well worthy to be found in such good company. Besides these masses, the centre of the hall contained many noteworthy specimen Palms exhibited by Thomas Hughes, the gardener to George W. Childs.

But as this was a *Chrysanthemum* show the interest centered upon these plants and their blooms. Probably no one ever saw a better group of *Chrysanthemums* than those which took the prize for a collection of twelve plants in twelve varieties, and which were shown by James Verner, gardener to A. J. Drexel. These plants averaged more than six feet in diameter, and upon one of them 300 first-class blooms were counted. As a matter of record it may be well to give the names of this prize list: Miss Mary Wheeler, Grandiflorum, Robert Crawford, Mrs. A. Blanc, Robert Bottomley, Mrs. Frank Thompson, Mrs. W. Sargeant, Puritan, Lilian B. Bird, Mrs. Irving Clarke, Mr. Frank Wilcox. Every one of these plants were models in form and in natural gracefulness, in the perfection of flowers and the health of their foliage. Scores of other plants deserved special mention, but there was no question as to the superiority of this remarkable group. These prize plants were all grown with a single stem branching near the ground, and of course they are more difficult to grow than

where several shoots are allowed to come from the same root.

The blooms were shown in the small hall, which contained besides them some Roses and other decorations. Among the best of the decorations was a bank of Orchids, all well-grown and well-flowered plants, and most tastefully arranged by Mr. Evans, of Rowlandville. The twenty-five blooms of *Chrysanthemums*, one of a kind, which were shown by F. R. Sykes; the hundred blooms, one of a kind, shown by William Tricker, with the fifty blooms in fifty varieties, and fifty blooms in twelve varieties, both by the same exhibitor, were pronounced better than any similar groups ever before shown in this city. Some of the collections of cut sprays, especially a vase containing some half dozen blooms of Lilian B. Bird, were remarkably good. Twelve blooms of the new yellow Henry E. Widener, shown by Ernest Asmus, were noteworthy for their immense size as well as for their perfection of growth. The aggregate diameter of the twelve was said to be more than ten feet. The twelve varieties selected by Mr. Tricker for his prize lot of fifty flowers were John Collins, Lilian B. Bird, Eldorado, Dawn, Mrs. Wanamaker, Grandiflorum, Excellent, Miss Mary Wheeler, Kioto, Mrs. A. Carnegie and Etoile de Lyon. This is the first time the last named flower has been exhibited in Philadelphia, and although these specimens had not reached the size the flower is said to have attained in Europe, it attracted much attention for its good form and good color.

Among the winners of the principal prizes besides those already named were Coles & Whitley, Joseph Heacock, Hugh Graham's Sons, J. W. Colflesh, John M. Cleary, Henry B. Surman, John Shaw, Charles W. Trotter and E. A. Schneider. A special premium was awarded to Julius Roehrs for a new Hybrid Perpetual Rose and a certificate of special merit was given to E. D. Sturtevant for two unopened flowers of the rare *Aristolochia grandiflora*. The flowers at this stage have a striking resemblance to the figure of a swimming water-fowl, so that the common name of "Duck-plant" applied to this *Aristolochia* is quite appropriate.

Seedling *Chrysanthemums* were shown in large numbers, and some of very high quality. Some of the large growers do not seem to have as many novelties as usual, but evidently a constantly increasing number of persons are raising a few seedlings, and as a result we find each year some very valuable flowers of marked individual character, not only for exhibition kinds, but in the fancy varieties, of which the French growers have given us so many. The American raisers have been remarkably successful within a very few years in securing very distinct breaks and a number of varieties of very well defined character. The finely imbricated Chinese kinds for some reason have not been done well in the United States, the climate seeming, in the eastern states at least, to be unfavorable to them. Evidently we shall soon have a number of round incurved kinds fully equal to exhibition requirements, and we shall need to make a new class for such as Mrs. Isaac D. Sailer, with which Mr. W. K. Harris won the "Veteran Prize." "Japanese incurved" might be an appropriate name for the class. The flower is a perfectly incurved, flesh-colored ball, very full, and with somewhat narrow florets. Even the bush of these shown was furnished with flowers massive enough to grace the exhibition boards. Mr. John Thorpe was hampered by his distance from the exhibition hall, but his new seedling, George W. Childs, with its soft, rich crimson and large petals, will be enjoyed by many for its rare and much desired shade, as well as its satisfactory form. His reflexed seedling, Ernest Asmus, is quite unique—a bronzy chrome. Peter Henderson & Co. gained a silver medal for Annie May. This flower, which originated with Mr. J. Forsterman, Newtown, Long Island, is a very full primrose yellow, with a bright apricot centre, large and distinct, slightly reflexed. Mrs. T. Monohan had a number of good flowers, and prizes were given to Mrs. I. G. Whildin, a primrose yellow form of Source d'Or. Black Beauty, of the same grower, also had a prize. It is a deep, full crimson, with lighter reverse well incurved. Mrs. Louis Childs Madeira was a golden yellow Chinese incurved, with a most remarkable solidity, and if well grown it may possibly be very valuable.

Mr. W. K. Harris and Mr. Robert Craig each scored the same number of points on six plants of new seedlings, so nearly were the two fine collections balanced. Mr. A. H. Fewkes, Newton Highlands, Massachusetts, exhibited a few seedlings of promise. Waban, a rose-colored incurved, in the way of Mrs. C. W. Wheeler, was excellent, as was another, a small ball of sulphur yellow, with orange centre.

James Brydon, gardener to Mr. J. Simkins, Yarmouthport, Massachusetts, exhibited some perfectly grown blooms and seedlings, etc. E. A. Wood, West Newton, and H. A. Gane, of the same city, staged very satisfactory seedlings, as did H.

Tong, gardener to Mr. W. L. Scott, of Erie, Pennsylvania. His rose colored flowers, while not large, were distinct and pleasing. Curiously different were the airy blooms of the Massassanqua Garden, Erie, Pennsylvania, and the white Ben d'Or of this selection, very noticeable. Mr. T. H. Spaulding exhibited his valuable novelties which attracted so much attention and gained the prize at the Orange show. He had also Mrs. Frances Spaulding, a fine yellow sort, rich colored, light, but full. Scattered through the exhibition were many other seedling plants of sufficient merit to deserve a special description in almost any other company.

New York.

S.

Notes.

The Report of the proceedings of the Boston Convention of the Society of American Florists has been received. It makes an attractive and instructive pamphlet of 140 pages.

It seems curious to read in an Austrian journal that while herbaceous Pæonies are common in England, France and even Germany, they are scarcely ever seen in Austria except in one or two private gardens.

A correspondent calls our attention to the fact that a Ginkgo-tree in the garden of Mr. Robert Johnston, of Providence, has produced crops of fruit since 1887. This tree and its male companion were imported from France in pots in 1849.

Dr. H. Mayr, Professor of Silviculture in the University of Tokio, and author of an important work on the forests of the United States, will return to Europe during the coming year to assume a position in the forest-administration of Bavaria, his native land.

It is said that dried flowers of *Lilium bulbiferum* and *Hemerocallis graminea* are sold in Chinese towns, woven together in braids of some five inches long. They have local renown as a remedy for diseases of the lungs, and are also used by cooks to flavor dishes of meat.

Peter Kieffer, well known as the introducer of the famous Pear which bears his name, died in Roxborough, Philadelphia, on November the 7th. Mr. Kieffer was born in Alsace in 1812, and came to America in 1834. He built up an extensive business, and was widely known as a pomologist.

Some plants which are very susceptible to a chill in the spring when they are young become quite able to endure the frosts of early autumn. We have observed that several plants of *Cobæa scandens*, which cover porches on the south or east sides of a house, still hold their green leaves, and what is more, are showing an abundance of flowers in this latter part of November.

A correspondent of the *Illustrirte Gartenzeitung*, of Vienna, says that in a private garden, of which the exact locality is not given, there bloomed this year for the first time a Clematis of unusual color. It is a hybrid of two years' growth from seed, and the large blossom, more than four and a half inches in diameter, is of a uniform dark crimson, similar to the color of the flowers of *Rubus odoratus*.

The Botanical Garden at Prague, which contained a fine assortment of hardy as well as greenhouse plants, was totally ruined by the great flood which in September last swept away the famous old bridge over the Moldau. For four days the water lay two feet deep above the greenhouses and plantations, and in the lowest parts of the arboretum it remained for ten days, to the entire destruction of almost all the plants.

In commenting on the formal style of gardening which he was so largely instrumental in driving out of fashion, Horace Walpole amusingly says: "In the garden of Marshal de Biron at Paris, consisting of fourteen acres, every walk is buttoned on each side by rows of flower-pots, which succeed in their seasons. When I saw it there were 9,000 pots of Asters or *La Reine Marguerite*—that is to say, what we now call China Asters."

Mr. W. J. Green, horticulturist of the Ohio Experiment Stations, in the summary of his report on Raspberries says that the Black Cap varieties now considered the most reliable are: Gregg, Hilborn, Ohio, Palmer. The red sorts that succeed best generally are Turner and Shaffer; the best for shipping are Brandywine and Marlboro. Muskingum, Royal Church and Thompson's Early Prolific are the most promising of the newer varieties.

According to the New York *Tribune* the increase of grape production in California has by no means decreased the amount of our importations from foreign lands. On the con-

trary, while twenty years ago not more than 500 barrels of grapes were annually brought from Spain, this year there will have come from the one port of Almeria alone no less than 180,000 barrels of the fruit. The importations are sold by auction, and bring from \$3.50 to \$16 a barrel.

The autumn colors of trees and shrubs are so striking that we sometimes overlook the herbaceous plants which add splendor to this season. *Lysimachia clethroides* is something of a weed, but just now a mass of it cannot fail to arrest attention by the rich crimson and yellow of its leaves. The little blue Plumbago, too (*Ceratostigma plumbaginoides*), which was covered until frost with its deep blue flowers, now makes a carpet of crimson deepening into maroon. This is a good plant for half shady places, where some low-growing thing is needed to cover the ground.

A German horticultural journal recently spoke with high approval of the so-called "American Giant Cyclamen," *Dodecatheon Clevelandi*, which, it said, would for the first time be offered to the trade this year by American nurserymen. It is not a Cyclamen, of course, but has gained its popular name from the fact that its large violet-blue flowers, with yellow and black centres, somewhat resemble Cyclamen flowers in shape. It is a native of California, discovered about three years ago, and is a hardy perennial which thrives best in rather shady localities. It bears from six to ten blossoms on a leafless scape about fifteen inches in height.

Worlidge, an English horticulturist who wrote in the year 1677, suggested that the name "Guelder-rose" (still commonly applied to the Snowball, *Viburnum opulus sterilis*) was not improbably a corruption of "Elder-rose," as the flowers of this *Viburnum* resemble those of the Elder. Some modern etymologists have adopted this explanation, and it seems supported by the fact that the name is perhaps more often written "Gelder-rose" than "Guelder-rose." But others derive the term from an old belief that the flower first came from Guelderland in Holland, and point as evidence to the Dutch name *Geldersche-roos* and the French *Rose de Gueldre*.

An article in a recent number of the *Gardeners' Chronicle* says that the demand for trees for planting has vastly grown of recent years and promises still further to increase in the future. One firm of nurserymen, whose establishment, which is yearly being enlarged, lies not far from Carlisle, now annually plants out more than two million seedling Larches, between two and three million Scotch Firs, one million Spruces, the same number of Corsican Pines and of Austrian Pines, a hundred thousand Douglas Firs, and millions of Thorns, Beches, Sycamore Maples, Ashes and other hardwood trees. This stock is eventually distributed not only through Great Britain, but through the United States, Canada and the various colonies.

We have elsewhere shown that it is important to give the children of our public schools some elementary instruction concerning trees, and especially the native trees which grow all about them. It is an encouraging sign that lectures on trees and forests now form part of the exercises at teachers' institutes in many places. Mr. Fernow not long ago addressed an audience of 600 teachers at Norristown, Pennsylvania, and this will doubtless inspire a great many familiar talks by a number of these teachers to their pupils. Miss Graceanna Lewis, of Media, Pennsylvania, is prepared to give to schools or private classes a course of four lectures on Oaks, Maples and Beeches, with original illustrations showing the form, size and color of the leaves of each species. The multiplication of such influences and efforts is greatly to be desired.

In the October number of the *Illustrirte Gartenzeitung*, of Vienna, under the caption "The new *Magnolia Fraseri*," we read that "this novelty" bloomed last spring in Philadelphia; that a specimen of it stands in Bartram's garden, in that town, and two others in Germantown, and that one of the latter "yearly blooms in profusion, but has not yet ripened seed." It is true that *Magnolia Fraseri* is not often seen in cultivation, and for this reason the Philadelphia specimens (which show it to be hardy far northward of its native habitat) are of interest to horticulturists. But it is hardly correct to describe as "a novelty" a *Magnolia* which was discovered by Bartram in 1776, was introduced by him into England in 1786, and was sent by the elder Michaux to France in 1789. Readers of the *Gartenzeitung* may easily be misled into thinking it a genuine novelty of perhaps Japanese origin. Its true home is in the southern Alleghany Mountains, and especially along the streams which flow from the Blue Ridge, the Black and the Big Smoky Mountains. It is there called the Mountain *Magnolia* or the Long-leaved Cucumber-tree.

Form in Flowers.

COLOR, form, size, habit and fragrance—these are the characteristics which, varying from flower to flower, produce in their different combinations the myriad types that delight us. Fragrance, however, may be set aside just now as not appealing to the sense of sight; for it is this sense which judges of beauty, and it is of the beauty of flowers that we intend to speak. And especially of beauty as shown in cultivated plants and modified by the hand of man.

The fact has been noted in these pages that the average eye is more impressed and attracted by beauty of color than by beauty of form. To combine colors well needs, it is true, the most highly cultivated taste; but the appreciation of single tints or of gradations of one or two plainly harmonious tones is a not unusual gift. Form, on the other hand, is seldom thoroughly appreciated except by trained eyes. In consequence, although the judgment of florists and their patrons is sometimes at fault in matters of color, it is in matters of form that it oftenest goes astray.

One of the facts which prove this statement is the constant confounding of mere size with beauty. In everything which appeals to the eye—from trees to churches, from jewels to mountains, from pictures to rosebuds—size is a potent element in arousing interest and admiration, its appeal to the sense of wonder being constantly confounded with an appeal to the sense of beauty. There are many cases, of course, when it is a true æsthetic factor, rightly augmenting delight. Other things being equal, an immense church interior or a huge diamond is more beautiful than a small one. All occidental men would doubtless give a similar verdict with regard to trees. Yet are not the Japanese now acknowledged to be a people of finer artistic sense than our own? And a Japanese art-critic in America has replied, when the small size of certain New England trees was excused, that to care for the bigness of trees was "barbaric"—their form was the primary, their size but a secondary consideration. But, however it may be with trees, it is certainly barbaric to lay too much stress on size

in flowers. When Nature herself makes them large she adapts shape and details to size. She draws their outlines with a bold hand, usually builds them of solid substance, gives them a massive array of pistils and stamens, and sets them on plants with sturdy stems and broad, firm leaves. Look at the Magnolia, the Night Blooming Cereus and the Artichoke if you would see big flowers as Nature loves to design them. There are exceptions to the rule, and Nature occasionally sets a big blossom on a small plant, but we instantly recognize the fact, and are more impressed by the oddity of such plants than by anything else about them. The best guide for man's efforts at improvement is always to follow the rule of Nature, not to imitate her exceptions. She can be graceful even when working with emphatic contrasts; but it is easier for him to succeed when he keeps to obvious harmonies.

There is a class of plants, just now very popular, which illustrates how gardeners may go astray in their improvements. These are the Tuberous Begonias. Differing much in the size of their leaves, these plants are naturally of low habit, with such weak flower-stalks that the blossoms droop, and with small flowers of somewhat irregular outline—that is, the type, as Nature designed it, was a small, drooping, irregular flower. The aim of the gardener, however, is to make it large, regular and erect. There are countless splendid "improved" Begonias in cultivation now, but the more one looks at them the more one feels that—apart from the variety of beautiful colors they show, to which all admiration is due—their cultivators have wasted their time. The increased size of the blossoms makes them look too large for the plants; their irregularity of outline and want of symmetry, so charming in smaller flowers, are displeasing on a larger scale, giving almost the effect of malformed flowers rather than of such as Nature had intended to be unsymmetrical; while the greater erectness of the blossom had destroyed its grace without giving it real dignity. But we are told the ultimate aim of the cultivator—true erectness and perfect symmetry—will soon be achieved. And if so, what will be gained? A commonplace-looking flower, with characteristics similar to those of a dozen others, in place of an individual, peculiar type that will have been "improved" out of existence. Big regular blossoms, holding their faces "well up," will undoubtedly be more "striking," but they will no longer be Begonias for any one who, beneath a name, cares to find a distinct floral type.

Of course, too, these Begonias are being doubled, and with their doubling the last traces of their identity will disappear. But it is almost hopeless to protest against this, the most common sin of cultivators. Who, that cares for types as expressions of Nature's creative power, and who that has any eye for beauty of form, can look with patience on the fashion which converts the exquisite cup of the Daffodil into a ragged lump of yellow, which mars the curve and fills the hollow of the Tulip's bowl with crowded petals, which "improves" the bell of the Hyacinth until it is no longer a bell, and the four-pointed star of the Bouvardia till it is no star? How, one wonders, has the Lily-of-the-Valley so long escaped, and when will Nature's beautiful half doubling of the Water Lily be carried further, until the last of the golden stamens disappears? And may not a "full double" Iris be the next high priced novelty? Nothing, indeed, seems too dreadful to anticipate, now that Narcissi are advertised for their close resemblance to double Camellias, and the ruined form of a Tiger Lily, dubbed *flore pleno*, decorates the pages of the latest plant-catalogues. Double Azaleas we have long had with us, and double Snowdrops. And if the shape and habit of the Begonia are to be utterly changed, will not some one make the Cyclamen hold up its head and spread out its petals in an orthodox way?

We do not wish to imply that there are no flowers which may well be doubled, that increase of size should never be aimed at, or that habit of growth can never be improved. It is only to protest against excess and misdirection

Form should be a prime consideration always. It should not be confounded with symmetry; and yet the truth should be remembered, that certain sorts of irregularity, charming on a small scale, are ugly when increased size makes them more conspicuous. A weak habit is often a defect to be remedied, yet at times it constitutes the whole character, grace and beauty of the plant. The multiplication of petals may often produce an effect so different from that of the natural flower as to constitute a new type, and one of much beauty. The type of the Dahlia has not been ruined by doubling—it has been replaced by another type with a certain formal beauty of its own. But such doubling often does no more than spoil the first type by turning it into a shapeless mass like that of many double Narcissi. Even double Roses should not be so big and so solid that neither grace of habit, nor beauty of general outline, nor freedom in the disposition of the petals remains.

The Jesup Collection of the Woods of the United States.

ON Saturday, November 15th, the "Jesup Collection of the Woods of the United States" was formally opened to the public in the Museum of Natural History in this city. For several years past the specimens have been shown in the great hall on the ground floor of the old part of the building, but much of its space was occupied by other collections, so their arrangement was not advantageous, nor could the drawings which accompany them be displayed. Now, however, the Jesup Collection alone occupies this hall, space for the other things having been found in the new wing of the Museum; and the public can appreciate the full interest and value of the wood specimens themselves and of the accessory collections which explain the trees that produced them and thus vastly enhance their significance. The old hand-book (which is shortly to be revised for a new edition) named 412 species of trees native to our country. All these, with one or two exceptions, are represented among the woods, and a few additional specimens have been secured since the hand-book was printed in 1885. Almost all the specimens are as fine, as regards both size and condition, as could be desired, and those which are less perfect will eventually be replaced by better examples. While each specimen shows the natural aspect of the tree with its bark, the character of the wood is shown in the upper portions by longitudinal, horizontal and oblique cuts, one half of each exposed section being plain and the other polished. The value to architects and artisans of the products thus displayed can only be realized by one who has passed the long rows of logs in review, and seen how many, as yet unfamiliar to commerce, show great beauty or singularity in color and marking. Information with regard to the strength of each wood is given, moreover, by the results of mechanical tests and chemical analyses recorded on the label-card, where also the scientific and popular names of the tree are given, while its habitat is shown on a little map. These labels, contrived for this collection by Professor Sargent, to whom Mr. Jesup entrusted the formation and arrangement of the collection, received a prize at the Paris Exposition last year and have since been imitated in at least one European collection.

Next to the woods themselves the most important feature of the collection is the series of large water-color drawings, representing the leaf, the flower and the fruit of each species in their natural sizes, which have been painted—in every case directly from nature—by Mrs. Sargent. About two hundred and fifty of these drawings are now shown, and the completion of the series is promised for the near future. As attractions for the popular eye they may outrank the wood specimens themselves, for they illustrate the beauty and immense variety of our forest-foliage and blossoms in a very charming and artistic way. Yet their value to the botanical student will be equally great, for although much freer and more graceful in treatment than the usual botanical illustration, they are absolutely truthful and exact. One point of excellence deserves especial notice. This is the way in which, although only isolated leaves and flowers or flower-clusters could be shown, the habit of the tree is suggested. The specimens are posed, to use the only available word, as nearly as possible as they would show in nature, so that we see at a glance not only the aspect of leaf and flower, but the manner in which the tree bore them.

To supplement these paintings we are promised a series of large photographs illustrating the chief species of our trees as

they grow in their native home—a feature which again will delight the public, and will be of incomparable value to the landscape-gardener and the horticulturist. Of extreme interest, too, is the series of glass cases filled with examples of the way in which insects devastate our trees, the insects and their nests being carefully prepared natural specimens and the leaves upon which they are feeding being most skillful imitations. The same persons have been engaged upon these who prepared the collection of stuffed birds shown in their natural haunts which was presented to the Museum by Mrs. Stuart a few years ago.

It is impossible, of course, in a brief notice like this to explain the great interest which the Jesup Collection has for every student of Nature; but enough has been said, we think, to suggest, at least, its practical value in a number of different directions—to the engineer, architect and artisan, to the forester, horticulturist, landscape-gardener and botanist, and to the mere lover of Nature's works. There is no collection of the kind in Europe which is so complete and instructive as this one; and we think it may safely be said that there is none of any kind, scientific or artistic, in our own country which equals it for many-sided completeness.

About 1,200 persons were present at the opening on November 15th, and as many as the lecture-room could hold afterward listened to the first of this year's series of lectures by Professor Bickmore, of the Museum. The subject of this was, appropriately, "The Broad-leaved Trees of the American Forest," and it was illustrated by admirable pictures of forest-scenes and remarkable trees. No better engine than the Jesup Collection, especially if explained from time to time by free lectures of this description, can be imagined for the diffusion among our people of an accurate knowledge of our forests and a true love for them. Nor is there any subject with regard to which an increase of popular interest and information is just now more greatly to be desired.

A Slaughtered Giant.

OUR illustration on page 575 shows a *Sequoia gigantea* with choppers at work inside the cleft cutting their way through the trunk. This is not a tree of the first size, being less than twenty-five feet in diameter and about twenty at the point where it was cut. In point of beauty and symmetry it was one of the best of the surviving Big Trees. It stood until a year ago in the Tule River forest, Tulare County, California, and was sold by the private owner of the land to certain persons who wished to exhibit it. The plan was to take a section of the trunk, hollow it out to a shell and then divide it into convenient and portable pieces, so that it could be carried about and set up as a show. The project fell through, however, for lack of funds, and the section of the slaughtered tree never got beyond Visalia, in the county where it stood. It is now stored in that city. Let us hope that the original owner of the tree and its destroyers may some day realize that it will never again make such an exhibition of grandeur and grace as it did while towering above the spot where it began life as a seedling a thousand years ago.

The Sequoia Forests of the Sierra Nevada.

THE following paper was read by Mr. Frank J. Walker before the California Academy of Sciences on September 1st and published afterward in *Zoe*. Since that time the Tulare Reservation Bill has become a law, but it is not generally known that the Government still holds other forests of Big Trees which are quite as worthy of protection as those already included in reservations. Mr. Walker's paper places on record many facts concerning which every citizen of the United States should be informed, for these wonderful groves belong to the people of the East as truly as they do to the people of California. It was a laudable sentiment which made it possible for Congress to pass without opposition the act to rescue one of these groups of Sequoias; but, as Mr. Fernow stated to a Senate committee, there are economic considerations which demand with greater urgency that the protection of the Government should be given to many other forest-covered areas in these high mountain regions, because the water question cannot be solved without first solving the forest-question.

The accompanying map (page 573) gives the Sequoia forests as located by Mr. Walker. The squares represent

townships six miles square. Taking the estimates of the paper the amount of Sequoia forest in the reservation is 3,500 acres; the Government still owns 5,500 acres; the Government holds 4,500 acres which are otherwise claimed, while 24,000 acres have passed from Government ownership. The map also gives the boundaries of the Yosemite Reservation as lately extended. The reason for such extension, as may be plainly seen, is that it includes the sources and courses of the streams which find their way into the valley, and this will enable the Government to protect these waters from being destroyed or diminished or diverted to other use before they reach the valley.

In the Standard Guide Book to the Pacific Coast, of a late issue, we read this statement: "There are nine groves of Big Trees in California;" and in the descriptive sketch following this remarkable statement we find three of the nine groves mentioned as lying south of King's River, vaguely described as: The King's River grove, the grove in the basin of North Tule, and the grove in the basin of South Tule. There are in the localities named as containing three no less than seven distinct groves and forests of Big Trees, while in the enumeration given there is no mention whatever by the author of the several groves and forests of Middle Tule, Kern or Kaweah Rivers, nor of the most southern grove, on Deer Creek; in short, the omissions comprise some twenty distinct Sequoia groves and forests, aggregating an area of at least 25,000 acres. Few, indeed, of the inhabitants of Tulare County, where most of the forests are found, have any conception of the wide extent of their Sequoia possessions; probably not one person in 500 knows of the existence even of Big Trees on the Kern River slope, and many would dispute the fact—a fact I have never seen referred to in print—and yet there are no less than 2,000 acres in that region, and some of it the most dense forest-growth of *Sequoia gigantea* known to man. And so with other groves; many of them are to the general public practically unknown and unexplored.

It is my purpose in this paper to briefly mention what may be termed the forests of Sequoia, and the neighboring groves; and in making the distinction between forests and groves it will be necessary to draw a somewhat arbitrary line, and for this purpose we will classify as forests all areas of 1,000 acres or upward, and all below that as groves. According to this distinction we can safely assume that all forests of *Sequoia gigantea* are to be found to the south of King's River, and nearly all of them in Tulare County; and, with mere mention of the better known northern groves—the Calaveras, South Park, Tuolumne, Merced, Mariposa, Fresno and Washington—we will therefore confine our sketch to a description of this region only.

The first, going southward, and probably the largest compact body of all, is the Converse Basin Forest on the south slope of the South Fork of King's River, in Fresno County. The area of this tract is about 5,000 acres. These figures can at best be but an approximation. For most part the Sequoia country is so broken, and the variation of density of growth so great, and the limits so vaguely defined, that an exact estimation is almost impossible; besides, it is likely to be misleading from the fact that it represents, in some instances, what might be called a heavy continuous growth, while in others it is more or less broken and scattering. In nearly all cases there is found mixed with the Sequoia a plentiful growth of other timber, principally Yellow and Sugar Pine (*Pinus ponderosa* and *Pinus Lambertiana*), with a sprinkling here and there of Fir, Cedar and other trees. However, I have aimed everywhere to keep my estimates of areas well within bounds. This first forest, together with the one next in order, are owned by one of the leading lumber firms of California. And they are about to celebrate at Sanger the completion of their forty-mile lumber flume connecting their capacious mills in the mountains with the railroad on the plains. They propose to clean up everything as they go along, stripping the land bare, and moving their mills and extending their flume from point to point as the timber supply becomes exhausted. It will probably take years for them to reach the Boulder Creek Forest, so named from the affluent of King's River, on whose slopes it is found. The area of this forest and neighboring groves cannot be less than 1,500 acres, probably more. These two already mentioned lie together on the waters of King's River, in Fresno County, but the forest next to the south, the Fresno Big Tree Forest, is on the divide between the waters of King's and Kaweah Rivers, partly in Fresno and partly in Tulare Counties. Its original area cannot be computed at less than 2,000 or 3,000 acres, but so much of it has been stripped

of its timber that its limits are hard to determine. Here have been the principal milling operations in Sequoia for the past twenty years. Four sections of it, containing what is known as the "Fresno Big Trees," have already been reserved by the United States Government, it being the only reservation ever made in these southern forests for the purpose of saving the Sequoia. This is the reservation recently confirmed by the Honorable Secretary of the Interior, and containing the famous Big Tree known as "General Grant," said to be forty feet in diameter.

Passing on to the west side of Township 14, Range 28, we find along Redwood Creek a forest of some 3,000 acres. This most magnificent growth has also passed from the possession of the Government to private ownership. Farther south, we next come to a forest on the North Fork of the Kaweah River, where there are upward of 1,500 acres of Big Tree forest still owned by the Government. The whole township is timbered and well worth preserving, aside from the Sequoia.

A few miles southward brings us to the Giant Forest, which, although still in the hands of the Government, is claimed by individual locators, by reason of their locations having been made in good faith and filed previous to the withdrawal from entry of these townships, as explained hereafter. It is generally thought that they will substantiate their claims and acquire the land, and public sentiment seems to favor it. Passing to the Middle Fork of Kaweah River, we find several groves, some of which are still in the hands of the Government, but there exists on this branch no Sequoia tract that could properly be called a forest.

Southward, on the East Fork of the Kaweah River, we come to what is designated as the Mineral King Forest, from a mining district of that name, comprising, with the detached groves, some 3,000 acres; the main body is in Township 17, Range 30, the township whose recent restoration to entry gave rise to the movement culminating in the Vandever Sequoia Park Bill, lately passed in the lower house of Congress. In December, 1885, Commissioner Sparks, of the General Land Office, withdrew from entry eighteen certain townships, of which this was one. The reason for this suspension was the alleged fraudulent character of the surveys. We need not consider the condition of these surveys; but, from the character of the country, it would seem that the subdivision lines could be more readily run with a ruling pen than with chain and transit; and at that time the compensation for either system of survey was supposed to be the same. But one thing is certain—on many of the Government plats you will search in vain for any trace of Sequoia growth, even where the alleged lines run through sections now known to be heavily timbered with the Mountain Redwood. It is to this fact largely, no doubt, that the very existence of certain Sequoia forests has so long remained unknown to the public.

The fact that several of the suspended townships contained Big Trees had nothing whatever to do, so far as we know, with influencing the act of the Commissioner. But Commissioner Sparks "built better than he knew," and the ultimate outcome of his order of withdrawal has been to preserve, in the Government's undisputed possession, several forests of these Big Trees that would otherwise have gone the way of all the rest into the hands of speculators and lumbermen. Thus the matter remained in statu quo till the opening of the present year, the friends of Sequoia preservation resting easy in the fancied security of their position, inasmuch as the Department had expressly declared its policy not to restore to entry these lands in advance of an official examination. At the opening of the present year, parties interested in acquiring timber by some means secured the release of the suspension of Township 17, Range 30. It was restored to entry on May 23d, and in less than six weeks the entire Mineral King Forest was filed on by timber-land claimants, and the tract effectually cleaned up. While thus the greed for Big Tree timber was developing the supply was growing short, and the attention of timber prospectors was turned to other forests, and it was found that in the next township to the south there was a forest practically unexplored that offered the best field for their next work. The same measures that had proved so successful in opening up Township 17, Range 30, were forthwith set to work to secure this more valuable prize. At this juncture a few citizens of Tulare County took steps to thwart the attempted spoliation of the Sequoia forests. As the forest in Township 18, Range 30, was the one the timber men most wanted, the inference was reasonable that it was the best of all for the Government to keep. The ultimate outcome of its opposition has been the Vandever Bill, embracing in the proposed reservation two townships and four sections

to be set apart as a National Sequoia Park. This reservation includes the forest marked on the map as the Sequoia Park Forest, and also the larger part of the Homer Peak Forest, somewhere from 3,000 to 5,000 acres.

South of these, following the Sequoia belt, we come to the Dillon Mill Forest of over 1,000 acres, with but little remaining to the Government, and from which thousands of Sequoia fence-posts are being hauled this season. And still farther southward, partly in the south-east corner of the same township, and extending into the corners of three other townships, is the Tule River Forest. Much cutting and slashing for a period of years has here been going on; and during this time different mills have been drawing their supply of Mountain Redwood from this forest, and still by far the larger part remains. Here exists a noted centre of Sequoia growth known as the "McFadyen 80" (acres), estimated by lumbermen to have on it timber sufficient for 8,000,000 feet of lumber. Only one mill is running this season. This, with the Pixley Grove, we will estimate at 3,500 acres. About six miles directly south is the Putnam Mill Forest containing some 4,000 acres. A portion of this, that in Township 20, Range 31, is still owned by the Government, and is a very beautiful forest of over 1,000 acres. Next comes the Fleitz Forest, owned by a Michigan syndicate; to the south of which are groves owned by the syndicate known as the "Kessing," the several tracts comprising an area of some 4,000 acres. Here again, in the south-west of Township 22, Range 31, the Government possesses a forest of somewhat uncertain value and extent, known as the Indian Reservation Forest, and estimated at 1,500 acres. It is not generally known that there exists any Sequoia on the Kern River slope, but there are on that side at least 1,500 or 2,000 acres in groves scattered along the slope from Freeman's Valley southward for some fifteen miles. Only one of these tracts could be classed as a forest, that of Freeman Valley. Here is a tract of about 1,000 acres, a limited portion of which is probably the heaviest growth of *Sequoia gigantea* in the world. Unfortunately this also has passed into the hands of lumbermen. One grove more remains to be mentioned, not because of its intrinsic merit, but because of its location, it being, so far as known, the southernmost limit of Sequoia. It is that on Deer Creek, indicated on older maps as "Mammoth Grove." It contains less than 150 Sequoias, scattered over an area of perhaps 300 acres.

This completes the list. The Sequoia forests proper therefore extend over a belt of country beginning at Converse Basin on the north and ending with the Indian Reservation Forest sixty miles to the south. The groves and forests together in this region are upward of twenty in number, with an average distance between them of perhaps three or four miles.

Within this scope of country, a moderate estimate of the Sequoia area would be, according to the foregoing figures and including a few unnamed groves, 37,500 acres, divided between the several river systems as follows:

King's River.....	7,500
Kaweah River.....	14,000
Tule River.....	14,000
Kern River.....	1,700
Deer Creek.....	300
<hr/>	
Total acres.....	37,500

It has been sufficiently shown that there are in the state several forests and groves of Big Trees still belonging to the Government aside from those embraced in the Vandever bill. To ensure the safety of these, and to put them beyond the designs of timbermen, and, above all, to protect them from devastating forest-fires, it is exceedingly desirable that they be reserved and placed under expert supervision. We need no reminder that the greed of timber and cattle men will soon work havoc with what remains unless something be done to stay the devastation; and if we would save a portion we must begin at once.

Concerning the utility of the region embraced in these limits as the best natural reservoir for the storage of waters needed for irrigation we need not dwell. But for a moment let me touch on the suitability of the country for a park because of its charming natural attractions. You need hardly be reminded of this. The heart of the Sierra culminating in Mount Whitney affords grand scenery of peculiar charm and great variety. Here are three Yosemite's rivaling their noted prototype in many features, with a little world of wonders clustering around the headwaters of Kern, Kaweah and King's Rivers. We will simply mention the Grand Cañon of the Kern, where, for twenty miles, the mad waters of the river are walled in

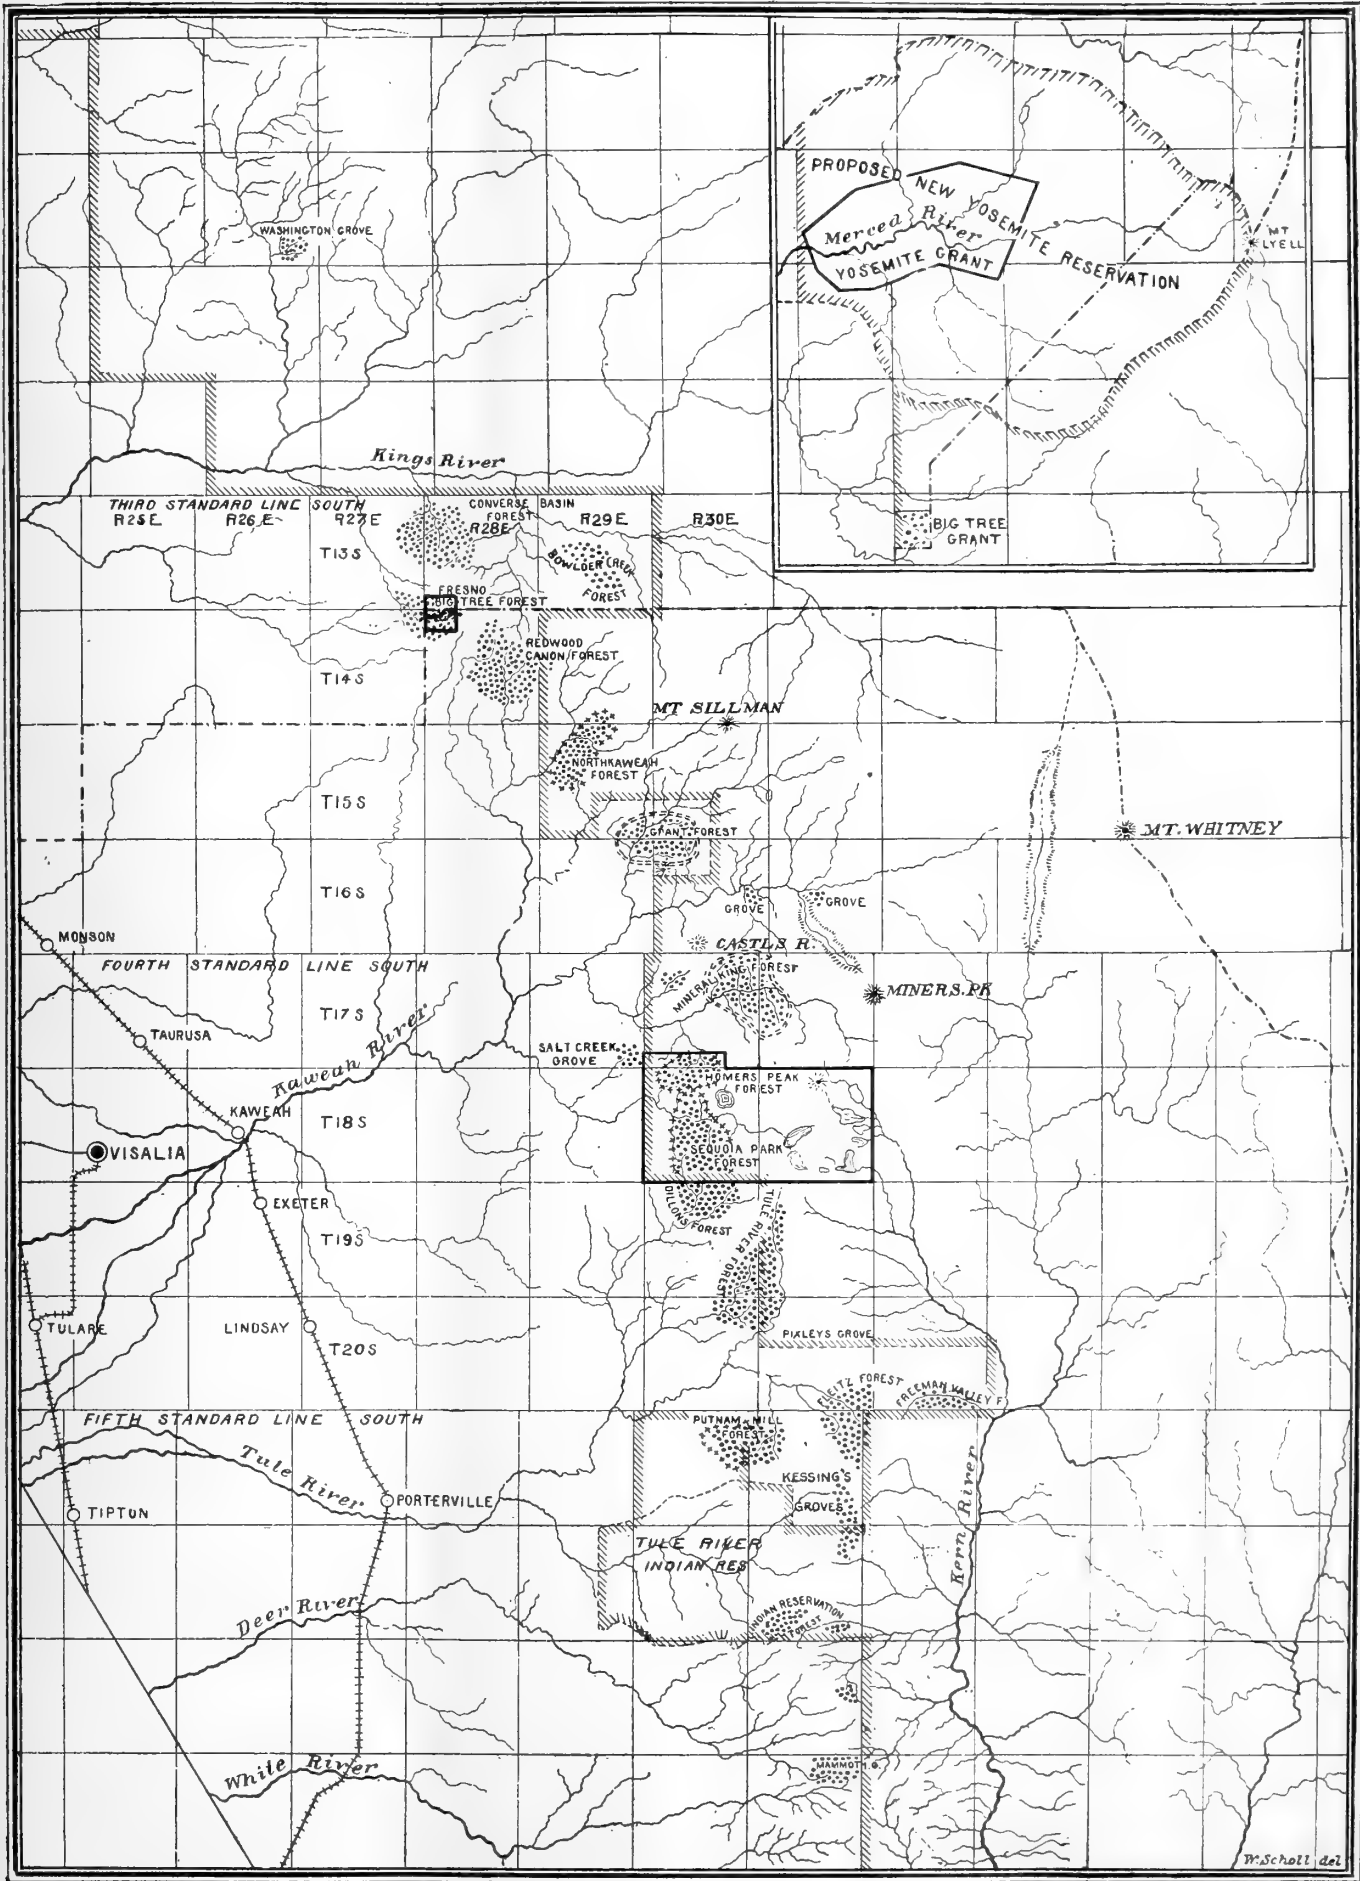

with the continuous battlements of the California Alps, crowned with nameless and unnumbered domes and towers. Then, only a few miles across the divide, extends the cañon of King's River with its wealth of impressive scenery, and some eight miles farther to the north lies the valley of Tehipitee—the gem of the Sierra—with its wondrous dome of rock rising in rounded majesty some 6,000 feet from the level of the river-cleft meadow at its feet. Yet a view of the most impressive and characteristic scenery of the region is to be earned by scaling one of the lofty peaks of the Kaweah Range. At least a hundred peaks here rise to altitudes exceeding 10,000 feet. One never can forget the impression who has once looked out over the California Alps from the pinnacle of Miner's Peak. As I once before said, in describing this scene: "Here amid the companionship of peaks one beholds with speechless wonder the spectacle beyond. No satisfactory view of the Whitney Range can be found from the San Joaquin plains. The intervening Kaweah Range veils the view of the higher peaks beyond. But here, standing on the crest of the Kaweah Sierra, one looks across the Grand Cañon of the Kern, and the encircling wilderness of crags and peaks is beyond the power of pen to describe. Mounts Monache, Whitney, Williamson, Tyndall, Kaweah and a hundred nameless peaks—the crown of our country—have pierced the mantle of green that clothes the cañons below, and are piled into the very sky, jagged and bald, and bleak and hoary—a wilderness of eternal desolation."

Plant Notes.

Some Recent Portraits.

THE November number of the *Botanical Magazine* contains a figure of *Acineta densa* (t. 7143), a magnificent Orchid from Costa Rica, belonging to the tribe of the Vandas, and related to *Lueddemannia* and *Peristeria*. It produces pendulous, dense-flowered racemes of large, pale golden yellow flowers. This is not a new inhabitant of gardens, having been introduced into England as long ago as 1849. It is still, however, rarely seen, although one of the showiest of all the plants of its class.

There is a figure (t. 7144) of *Eucharis Bakeriana*, a native of Columbia, and related to the well known *Eucharis Amazonica*, or, as it should be called, *E. grandiflora*. Another of the bulbous species of Iris (*I. Sindjarensis*, t. 7145), allied to *I. Caucasica*, *I. orchidoides* and *I. Palæstina*, is figured. It is a dwarf plant, with crowded, lanceolate, broad, distichous leaves and pale lilac flowers, discovered in 1865 in Mesopotamia by Dr. Hanskenecht, and introduced into cultivation by Max Leichtlin, of Baden-Baden. There is a figure of the dwarf variegated Bamboo (*Arundinaria Simoni*, var. *variegata*, t. 7146) best known in cultivation as *Bambusa Simoni*, a native of Japan, and introduced many years ago into the garden of the Paris Museum by one of the French Consuls in China, Monsieur Simon. It is a hardy, tufted plant, reaching in Europe a height of eight or ten feet and flowering sparingly. "In Algiers it is described by Rivière as forming rhizomes that bury themselves one and a half to two feet, and from which new culms rise in the beginning of May, which, during the first year, are simple, clothed with spathaceous sheaths, and attaining twenty to twenty-five feet in height. Toward the end of the second year these culms ramify in whorls from above downward and flower. The leaves are eight to ten inches long and quite glabrous." The specimen which served as a subject for the illustration is "from a magnificent plant grown by Mr. Paul in a Camellia-house at Cheshunt, the culms of which are fourteen feet high and as thick as the thumb"—a suggestion of the best way this plant, as well as many other species of the dwarf Bamboos, can be used in our northern states in decorative gardening. There is a figure of the well known *Pereskia aculeata* (t. 7147), a member of the Cactus family, and one of the first of the tropical plants introduced into Europe, it having been cultivated in the Royal Gardens at Hampton Court as early as 1696. In Kew, it appears, it has been cultivated ever since the foundation of that establishment, although there is no record of its having flowered there until last year. It is a straggling or climbing bush or small tree whose branches are described as climbing, but more generally it climbs by means of the hooked spines of the young branches. The flowers are an inch and a half in diameter, with pure white, rosy or yellowish white petals. The fruit is the size of a small gooseberry, globose, transparent, few-seeded and covered with small spreading leaves, the free tips of the sepals. The leaves are used as a pot-herb in Brazil and the berries are eaten in all parts of the tropics of the New World.

The Big Tree Forests (*Sequoia gigantea*).—See page 570.

As the editor points out, "It is singular that so common an American plant with an edible fruit should not have been introduced by the Spaniards and become an 'escape' in the Old World, where I think it would be naturalized with great rapidity."

The colored plate in the *Revue Horticole* of the issue of November 1st is devoted to the Mexican *Senecio Ghiesbreghtii*, a native of Mexico and an extremely ornamental species, which is now often seen in the gardens of southern Europe.

Foreign Correspondence.

London Letter.

TREES IN TOWNS.—Dr. M. T. Masters, editor of the *Gardeners' Chronicle*, lectured recently before the Royal Horticultural Society on the subject of Tree-planting in Towns. An enormous amount of material and labor are or have been wasted by planting indiscriminately all kinds of trees and shrubs, most of which prove incapable of enduring the atmosphere and other trials inevitable in town streets and gardens. The right thing to plant and the manner of planting are unknown to vestries and local boards, and many of these bodies have already learned by sad experience how ignorance, when it dabbles with planting, must inevitably come to grief. Dr. Masters' lecture will be published in the *Journal* of the Royal Horticultural Society. It will include an exhaustive list of such trees and shrubs as have proved to be adapted for cultivation in towns. It would be interesting to us to have the results of American experience in this matter.

PERNETTYA MUCRONATA.—Are American gardeners acquainted with the pretty berried varieties of this plant, which were raised in an Irish nursery about ten years ago? The type is, of course, well known everywhere as a first-rate hardy shrub which bears an abundant crop of bright crimson berries every winter if happily situated. Mr. Davies of the Hillsboro Nurseries, County Down, has added considerably to the value of this plant by raising from it a number of varieties remarkable for the rich colors of their berries. White, pink, lilac, purple, cerise and almost black berried varieties were obtained, and these are now becoming popular, not only for the open border, but as pot-shrubs for winter decorations in-doors. Plants a foot high, compact as Box and thickly laden with berries may be grown in a five-inch pot, and such plants are as attractive as any berry-bearing plants in cultivation. Out-of-doors the plants sometimes fail to produce berries, that is in some gardens. In Mr. Davies' nursery I saw acres of them about seven years ago, and every plant, from babies six inches high to large bushes as tall as a man, was a mass of fruit. It is probable that a sandy, peat soil is most conducive to fruit-production in these plants; such, at any rate, is the character of the soil in Mr. Davies' nursery. Variegated conifers were much better colored in this nursery than I remember to have seen them elsewhere. In Ireland the *Pernettyas* are almost as commonly grown for winter effect as *Solanum Capsicastrum*. The varieties are named Alba, Carnea, Purpurea, Macrocarpa, etc., names which are descriptive of the berries. They are now trying in America, if this has not been done already. [*Pernettya mucronata*, like other plants of the southern Hemisphere, is not hardy in the northern states.—Ed.]

CHRYSANTHEMUMS.—There will be over fifty large exhibitions of Chrysanthemums held in England during next week. The National Chrysanthemum Society will devote four days to a gigantic exhibition, conference, etc., to mark the centenary of the introduction of the Chrysanthemum into England. In most of the parks and public gardens of London special efforts are annually made to produce an imposing show of this most popular of all winter flowers. Kew, Finsbury Park, Victoria Park, Temple Gardens, with several other places of popular public resort, have each an exhibition of no mean order. The literature of the Chrysanthemum crops up everywhere at this time of year, daily papers, society papers, papers of every description commenting upon, discussing and offering advice on the management of the hundreds of varieties now cultivated. No flower, not even the Rose, has ever been more generally cultivated and admired in England than the Chrysanthemum is now. The taste for large, well formed flowers, combined with bright colors, which now prevails in England, was recently very much laughed at by the President of the Japanese Horticultural Society when on a visit to Kew. The perfection of Chrysanthemum culture in Japan is a large bush bearing an enormous number of small flowers. Such kinds as *E. Molyneux*, *Elaine*, *Avalanche* and *Mrs. G. Rundle* would not, he

said, find any favor with Japanese growers. In my opinion the finest Chrysanthemum ever raised is *E. Molyneux*. It is almost a miracle in form and color. Nothing in horticulture is more remarkable than the development of such a flower from the little yellow buttons of the progenitor of garden Chrysanthemums—namely, *C. morifolium*.

SALVIA SPLENDENS and *S. azurea*, var. *grandiflora*, are most useful plants in the greenhouse at this time of year. The rich scarlet flowers and bushy habit of the former are as effective as anything we have, whilst the bright blue flowers of *C. azurea* are charming amongst the commoner colors which prevail in the greenhouse in November. At Kew about a dozen species of *Salvia* are grown out-of-doors all summer along with the Chrysanthemums, and housed at the same time. The treatment that is good for the one is equally good for the other. These two genera and *Celosia pyramidalis* are the most striking features of the conservatory just now.

CATTLEYA WAROCQUEANA.—Better acquaintance with the plants distributed under this name and a comparison of their flowers with those of some of the forms of *Cattleya Gaskelliana* has led to the conclusion that the latter name must stand for both. In the time of flowering, the character of the pseudobulbs, the form of the flowers and the wide range of variety in their colors, there is no marked difference between what was introduced and distributed by Mr. Sander seven years ago as *C. Gaskelliana* and this new introduction of M. Linden's Company. At the same time, there are amongst the latter forms which differ from anything previously seen in what was introduced by Mr. Sander as *C. Gaskelliana*. We are indebted to M. Linden for additional proofs of the exceptional value of this sub-species as a garden plant. Some of the flowers recently exhibited by M. Linden showed a close resemblance to *C. speciosissima* (*Luddemanniana*).

ODONTOGLOSSUM CRISpum.—There is apparently no danger of this Orchid ever becoming extinct as a wild plant, for it must be as abundant on the mountains of New Grenada as the Primrose is in the copses of England. Hundreds of thousands of plants are imported into England every year, and they may be bought at the auction rooms at seventy-five cents a dozen. Ever since the year 1863, when the three collectors, Weir, Blunt and Schlim, found themselves sailing in the same steamer on the same errand, namely, to collect plants of *Odontoglossum crispum* for the Horticultural Society, Messrs. Hugh Low & Co. and M. Linden respectively, this Orchid has been imported in enormous quantities annually. What has become of the millions of plants thus poured into European gardens? At first many were killed by growing them in a stove temperature, but even now, when the conditions afforded under artificial treatment are the best possible, there are not in cultivation many examples of *O. crispum* that measure a foot in diameter. Is this plant naturally a short-lived one? Auction sales are not always the best means for stocking one's Orchid houses. The farming of Orchid grounds where the plants are wild enables the "farmers" to select the best varieties before the plants are dispatched to England or other countries to be sold as "unproved." On this side the best growers send to the auction rooms all the varieties that are not considered worth growing, keeping only those that are of good quality. It therefore follows that the beginner who returns from the auction rooms with "good established plants, bought for a few pence each," has got only the refuse of other collections. Of course they are Orchids all the same, and worth what they cost. Good varieties are costly in spite of the abundance of the plants in the market.

Cultural Department.

"Very Good" and "Best" Apples.

WE who are and have been working upon our cold northern border to extend the culture of tree fruits successfully into the region of hard winters occasionally feel, when we read the criticisms of some who are recognized as experts in pomology, that our labors are not thought of very great worth to the country at large. I have sometimes thought that perhaps some prejudice entered into the criticisms we meet with; and I have to console myself with recollections of the kindness with which such work was recognized, even in its small beginnings, by such noble leaders as Downing and Wilder. The former showed his strong recognition of the importance of these experimental labors when he bequeathed his pomological library and notes to Professor Budd; while, as for myself, nothing gave me more encouragement than the receipt, four years since, of a letter from Mr. Wilder in

which he said: "You are doing the country great good by publishing the results of your experience in the growth of fruits on our cold northern border line." Of course, I felt that the plural form of the pronoun rightly embraced and included such men as Gibb, Tuttle, Jewell, Sias, Gideon and numerous others; some of whom, though doing much good

where such fruits are not required. The criticisms they make are natural enough from their point of view; but they emphasize them so persistently, and with so little real acquaintance with conditions and circumstances, that they partake of the character of assaults, and tend to discourage where Downing and Wilder saw good reason to encourage experiment.

Felling one of the Big Trees (*Sequoia gigantea*).—See page 570.

work, have not contributed as much as might be wished to the written record thereof.

At this time, however, I only desire to say something that has been impressed upon my mind by the frequent complaint made by certain pomological writers in regard to the quality of iron-clad tree fruits. These writers, without exception, live

The charge against the iron-clad apples as being deficient in dessert quality is true, and it is not true. It is true, just as the same criticism made by Englishmen against American apples is true. It is not true just as these English criticisms are not true. By this I mean that we are shipping to England a good many apples that do not approach in fine dessert

quality the best and most carefully grown among the choice table apples of Europe. But the English public buys and pays good prices for some of our poorest American apples. The Ben Davis, even where it is most at home and is well grown, is scarcely "good" for eating out of hand, yet for shipment to England it stands among the first in point of demand and in price. The Baldwin at its best, as grown in south-western Maine, is perhaps the apple first in demand for trans-Atlantic export; yet I never heard or saw the Baldwin named in a list of our best dessert apples, while the English experts think less of it than its American critics. "Its size, color and keeping quality are what sells it" is the verdict upon both; and the Rhode Island Greening, in its best form (yellow fleshed), though far superior to the Baldwin, hardly equals it in price, either at London or Liverpool. Northern Spys and Kings stand higher, but do not touch or approach the standing of the best Newtown Pippins.

Not so many as ten of the iron-clad Apples are well known outside of the region where they are chiefly grown. They are generally judged upon the character of the Alexander, the Red Astrachan, the Oldenburgh and the Tetofsky. When we ask critics of these apples what they mean by the poor quality of the Russian or iron-clad Apples, they invariably refer to these. Yet Astrachans, Oldenburghs and Alexanders are very salable apples in all our large markets. The Wealthy is never referred to, but the Wealthy is better than the Baldwin. The Prolific Sweeting is unknown or ignored, yet no fall sweet is its superior in appearance, or in quality for dessert or baking. St. Peter, Switzer, Longfield, Winter St. Lawrence, Shiawassee, Gideon's Peter have been grown long enough to be easily had for testing, yet they are not named. But they will all rank with the sorts that stand uncontested as "very good" or "best."

But how many of these "best" dessert apples are on record in American pomology, which scores altogether more than a thousand named and described varieties? Let us take the American Pomological Society's select record of 369 varieties and count them. There are just twenty-one of them, and the odd one is foreign. In the "very good" list there are 155 varieties, of which twelve are foreign and five are iron-clads, leaving but 132 apples in this class of our native apples outside of the native iron-clads. In all, then, of our American named apples (including Canadian varieties) there are but 142 that are ranked above the humble "g" which marks our culinary fruit of this class.

Our native iron-clads, then, are not below the average of the Society's select list. As to the Russians, no grade is yet assigned to any of those recently admitted to the record. This shows it to be the opinion of the Society that the time has not yet come to fix their place. That is precisely the opinion held by those who are most interested and have had the longest experience with them. As the students of these apples take this position, why should those of less experience and knowledge regarding them be in such a hurry to give judgment against them? Of the whole list no American, unless it be Professor Budd, knows the exact season or value of twenty of the iron-clads of north-eastern Europe.

The Root Rot of Salsify.

DURING the past two years gardeners have complained of much decay in Salsify roots. Before the crop is harvested some of the plants will be seen to have a pale yellowish appearance and soon the further growth of the top ceases. In the worst cases all of the plants are a mass of rottenness long before the time for harvesting comes.

An examination of the roots shows that the decay usually begins at the lower end of the main root and quite rapidly works its way up to the crown. The decay is particularly soft, very complete and somewhat offensive. In the decayed portion there is little left of the structure of the root, excepting the scattering vessels and woody fibres, which, having thick walls, resist the corroding action of the agent of decay. No threads of any Fungus are to be found in recently disorganized tissue, but thin sections of the decaying substance of the root reveal under the microscope great numbers of bacteria. The first effect of the germs is to dissolve the substance that holds the cells of the root tissue together. After this they penetrate the wall of the cell and increase so rapidly as to literally fill the infested cell with these minute bodies, each in constant motion. A view of such a cell under a high power of the microscope suggests the activity one may see in a bee-hive during the best week in honey-making.

Inoculations were made of the bacteria upon the healthy tissue of other roots, and the infection spread from each point

with remarkable rapidity. Other kinds of vegetable substance were treated in like manner, and it was found that all of the following were susceptible, but not to an equal extent: The fruit of the Egg-plant, Sweet Potato, White Potato, Onion and Apple. The egg-plant was entirely decayed in thirty-six hours, and the apple least affected. The progress of the decay of the various substances was in the order in which they are named above.

As to the beginning of the decay in the Salsify-roots nothing can be said but the decay as found when well under way is not attended by any insect or any Fungus, save the bacterium, which latter is constantly present in the decaying tissue, and small portions of this decaying substance are able to convey the activity to healthy tissue of the same host and to representative types of vegetables, fruits, tubers and other roots.

What needs to be done in the way of a remedy it is not easy to say. As the trouble probably begins below ground, and some distance from the surface, it is difficult to detect the presence of the trouble at the outset. The paling of the herbage should suggest an examination of the root, and if it is found decayed the plant should be dug and destroyed. It is not likely that any fungicide can be sprayed with good effect upon the plant. It is possible that large quantities of manure in the soil may have furnished breeding ground for the bacteria of decay. It would therefore be well to test the value of some commercial fertilizer upon this crop. As the decay is remarkably contagious, care should be exercised in discarding all roots at harvesting, and it should be borne in mind that the virus is active upon other similar food substances.

Byron D. Halsted.

Carludovicas.

THESE form a handsome genus of foliage plants, which, from their general appearance, give the impression of being Palms, though in reality they belong to a division of the *Pandaneæ*. The Carludovicas are of free and rapid growth when under congenial conditions, and are deserving of more extended recognition as decorative plants than they have yet secured, for they are not only highly ornamental as stove or conservatory specimens, but may also be used in an out-door foliage bed during the summer, provided they are not exposed to the full force of the sun. Of course it would not be a wise measure to take a Carludovica from a close, warm house and plant or plunge it out-doors for the summer without any further preparation, as the result would probably be unsatisfactory; but if treated as all foliage plants should be treated before they are planted outside—that is, if they are gradually hardened off by means of increased light and ventilation—they may be used for out-door decoration with very pleasing effect and without injury to themselves.

In-doors they prefer an open, well-drained soil which contains a fair proportion of peat, and when the plants are well established an occasional watering with manure-water is beneficial and tends to keep up the color of the leaves. Carludovicas are propagated by division, as most of the varieties sucker freely, or by means of seeds, when these are available; but as the seeds are seldom offered the first-mentioned method is that most generally adopted.

Among the varieties in general cultivation, or rather, most frequently met with, as none of them are particularly common, *C. humilis* is the best. It bears leaves of rich light green color, one to two feet long and nine to eighteen inches wide, and deeply cleft or bifid at the apex, making a shapely plant, bearing some resemblance to a Licuala, though without the thorny leaf-stems of the latter. *C. humilis* is possibly somewhat more tender than the following sorts, and some discretion should therefore be used in regard to its out-door exposure.

C. palmata is another handsome plant, with large palmate leaves that are deeply divided into narrow segments, the entire leaf being dark green in color. The leaves of this species are thrown up on long foot-stalks and have a very graceful effect. *C. palmata* also has some reputation as the plant from which the so-called Panama hats are said to be made. The young leaves, cut for this purpose, after having passed through various processes of steeping, bleaching, etc., are split into narrow strips and then plaited into hats.

C. rotundifolia is also a fine decorative plant, with general characteristics similar to the preceding sort, though the plants are quite distinct, as close examination will show. *C. rotundifolia* has fan-shaped leaves of a bright green color and deeply cleft into narrow pendent sections. It is not quite so large a grower as *C. palmata*, the latter sometimes attaining a height of twelve to fourteen feet under favorable conditions, while *C. rotundifolia* seldom exceeds six to eight feet.

One of the oldest species of this genus is *C. atrovirens*, a plant that deserves its specific name, for the deeply bilobed leaves, as well as their foot-stalks, are of an extremely dark shade of green. The leaves of this species are gracefully arched, and from a distance have some resemblance to the foliage of a *Curculigo*. *C. atrovirens* is a free grower, and usually produces a number of suckers around the base of the parent plant, so that its increase is a comparatively easy matter, and as the foliage of this sort is quite hard it makes a useful plant both in-doors and out.

In addition to the few species here mentioned there are some others in cultivation, of which one, *C. purpurata*, is somewhat similar to *C. atrovirens*, but differs from it in having reddish purple leaf-stems in place of the dark green ones of *C. atrovirens*. Another fine variety of more recent introduction is *C. Plumieri*, which makes a very handsome plant, but it is not so easily obtained as most of the above mentioned species.

Variation in Color of Chrysanthemums.

The Garden (London) of November 1st contains an interesting communication from Mr. Edward Molyneux, the well known grower, as to variation in form and coloring of Chrysanthemum flowers. Mr. Molyneux is a close observer of this family of plants, and his notes, always interesting, may usually be accepted without question. His conclusion in this article, however, "that the whole cause of the variation of color lies in the date the buds are formed" is not entirely correct. It is, of course, well known to every one having experience in cultivating the Chrysanthemum that the buds formed and selected at different seasons will produce forms and colors sometimes almost radically different from each other, and, as a matter of fact, crown-buds of most varieties produce flowers almost always differing in some respects from the terminals in form. Mr. Molyneux's conclusions might be correct as to color variations if only plants grown under usual greenhouse conditions were considered, and perhaps he had plants under glass, as usually cultivated, in mind when writing the article. But there are other conditions of culture, and any one who has grown these flowers, either under shade or in the open, must have observed that besides the difference in the time of bud formation more or less light is an important element in the coloring of many varieties, especially those of lilac and red shades. Persons having greenhouses with imperfect or not very clear glass will often notice a fading out or lightening of some colors, but this difference becomes much more marked when the direct rays of light are entirely excluded, as under a temporary canvas or other covering so often used. Having grown fine lots of flowers under a temporary tent, and others in a sheltered south border practically in the open, though with some overhead protection, I have been interested in noting the colorings of the various varieties under these two extremes of exposure. My experience under glass has been so slight that this will not be considered.

The variety Puritan seems to have been first exhibited in England this year, and its varied colorings excited some comment and were the immediate cause of Mr. Molyneux's note, and he explains that "the early formed buds give blooms characteristic of its name, . . . later buds give the deep lilac color sometimes seen; . . . both colors are sometimes to be found early in the season, for the reason that this variety is an early flowering sort, and although both kinds of bloom can be had at the same time and from buds of different dates, those earliest formed require longer to develop from the bud stage." That is not the nature of Puritan with me at least. My early flowers of this variety in the open were a full lilac; they were after covered, and all color disappeared except a slight trace on the lower petals. Those from later buds under the tent are of the purest white with no trace of lilac, and this has heretofore been the rule with this flower in that position; if grown near the edge of the tent there is usually a faint flush of lilac on the lower petals.

Admiration is a beautiful old variety if grown under cover, with a white centre, shading outside to a delicate pink. In the open, regardless of any time of bud-forming, it makes flowers of a turbid blue-red and is entirely destitute of any beauty. Madame C. Audiguier seems to be a freaky variety, which has sometimes run counter to my experience with other varieties, for I have had it well colored under cover and nearly white in a sheltered corner, but fully exposed. The effect of shading is not visible on the whites or yellows usually, though it slightly lightens the latter and clears out flesh tints as in Domination. It is in some forms of red that I find flowers are more seriously affected. Val d'Andorre, Lord Byron and flowers of similar

character are apt to be streaky and off color no matter when buds are taken. The favorite variety, J. Collins, is not seriously affected, though it loses some of the metallic tints so characteristic when grown in the open. An early bud which I picked to-day was richly colored in remarkable contrast to flowers from later buds, which, under the same shelter, have only developed a peculiar tan color. All of which, of course, serves to prove that different conditions and different cultivation in the garden produce different results. Among the Chrysanthemums one can find infinite pleasure, from early spring till the last flower is withered, in watching the different phases of these wonderfully varied plants. It is not surprising that the Chrysanthemums, single varieties of which have such chameleon-like habits, are growing constantly in favor of cultivators.

J. N. Gerard.

Notes from a Wild Garden.

THE showy Lady's Slipper (*Cypripedium spectabile*), to which repeated reference has been made in GARDEN AND FOREST, is rarely seen in cultivation. This neglect can probably be accounted for in the main by the limited areas in which it is found, that it is nowhere abundant and that it rarely bears fertile seed. But a little experience I have had seems to indicate that it may be readily propagated. Five or six years ago I introduced a plant to my garden. The first year it sent up but a single stem; but the stems have since been increasing at the rate of about one a year, and the past season there were five, all of which flowered, two or three bearing two flowers each. A division of the roots (which might have been made sooner to advantage) would of course now multiply them indefinitely. The plant, in the first place, was given a prepared soil of rich leaf-mould in a damp and partially shaded situation, and carefully mulched each successive year.

The corm of the Green Dragon (*Arisæma Dracontium*), of which mention was made in former notes, was reset the last season, as before, in a rich damp soil, and made a most remarkable growth. The terminal and principal leaf measured eighteen inches across, the leaflets all gracefully drooping with their own weight. The rigid upright stem, three-quarters of an inch in diameter near the ground, was over two feet in height and bore a second well developed leaf. The plant never failed to attract attention for its oddity. Of fair size when first introduced to the garden, it has been increasing in size each succeeding year. The corm the last season measured three inches in diameter or about the size of the mouth of a tea-cup.

To whom has it ever occurred to cultivate the Wood-Nettle (*Laportea Canadensis*) as an ornamental plant? And yet it only awaits a trial to prove to any one its effectiveness as a decorative plant for certain positions in the garden. Its merit was discovered to me only by an accident. In removing another plant from the woods some of the roots of the former remained in the soil, which, springing up, were allowed to grow, and for several years past it has formed a singularly effective clump of rich green foliage about four feet high. The ample leaves are still larger, the stems are taller and the foliage much increased by cultivation, and the great, spreading cymes of the strange-looking greenish flowers—the striking feature of the plant—are also much enlarged. It is enough to say a plant that will force the question from the most casual observer, "What is it?" is a success and needs no further commendation, and such is the Wood-Nettle in cultivation. Give it a rich soil in a damp, shady spot, and all it asks is to be let alone.

Notes on Shrubs.

A FEW plants of the Heath family are well known for the beautiful effects of autumn foliage which they assume. While some species have valuable characteristics of this kind it does not follow that all the species of any genus have any similarity in their manner of autumn coloring and defoliating. The foliage of many of the Blueberries and Huckleberries assumes bright red, crimson or orange colors in the late autumn, and it often persists much longer than the bright hued leaves of a majority of plants of other genera.

In the latter part of October and the early portion of November the High Blueberry (*Vaccinium corymbosum*) often exhibits splendid coloring which is hardly surpassed by the Sumachs, whose leaves fall much earlier. Although the common Low Blueberry (*V. Pennsylvanicum*) often brightens the waste places which it covers it is not so satisfactory under

cultivation that it could be recommended as an effective under-shrub in late autumn. It is valuable simply for its fruit, which is the staple and earliest Blueberry of northern markets. The leaves fall quite early, a habit which appears to be possessed by the alpine and very dwarf *V. cæspitosum*, and also by *V. Canadense*, which in some respects is very similar to the Low Blueberry. The leaves of the northern Bog Bilberry (*V. uliginosum*) are also quite early deciduous. The Deerberry or Squaw Huckleberry (*V. stamineum*) apparently loses its leaves without taking any bright colors. It is almost impossible here to get perfect fruit or seed of this species because of some small lepidopterous larvæ, which live within the berries and destroy them before they are fully ripe. The rare and edible-fruited *V. hirsutum*, from the mountains of North Carolina, is as beautiful in the richness of its autumn coloring as *V. corymbosum*, and it also has the merit of retaining its leaves until those of nearly all other deciduous species have fallen. The true Huckleberries (*Gaylussacia resinosa* and *G. frondosa*) hold their leaves well and they also assume pleasing purplish and orange colors.

The Sorrel-tree or Sour-wood (*Oxydendrum arboreum*) is hardly surpassed by the Flowering Dogwood in the depth and richness of its autumn foliage, but the leaves drop easily, and the plants here are leafless comparatively early in the season. Many of the leaves of the Stagger-bush (*Andromeda Mariana*) hold until quite late in November, and are often quite brightly colored; and perhaps no deciduous species in the whole family is more showy than *Leucothoe racemosa*, with purple, scarlet and orange foliage, which persists throughout the month. Although the flowers of this plant are of no ornamental value it is nevertheless a desirable one for planting in shrubberies and other situations where very late autumn color is a desideratum. It is easily cultivated, and once established it slowly increases and spreads by underground shoots. The beautiful flowering *Andromeda speciosa* retains its leaves in a fresh appearing condition quite as late as *L. racemosa*. Many of them gradually become yellowish, but there is no display of color.

Among the hardy deciduous Rhododendrons or Azaleas there appears as a rule to be little very attractive and constant character in the late color of the foliage. Some of them become purplish or reddish, others dull yellow or brown. The beautiful flowered *Rhododendron Vaseyi* possesses handsomer autumn foliage than any other, as it first turns purplish and later to a deep crimson, and generally persists well into November. The leaves of its nearest American ally, the Rhodora, gradually dry without coloring, and leave the plants leafless quite early in the season.

Arnold Arboretum.

J. G. J.

Potentillas.—It may be a help to those who know this bright, free-blooming family of summer-flowering perennials to have a short list of some of the best and most distinct varieties. There may be others quite as good, and I should be pleased to know of them through other correspondents. All the varieties enumerated are double, as the single ones, although very bright, are not nearly so lasting. The foliage of all the Potentillas have a close resemblance to that of the Strawberry, to which it is nearly allied. The flowering season is during the summer and early fall. Gloire de Nancy, golden yellow, large, full flowered; Jane Salter, orange shaded with scarlet, medium size, free; La Vesuve, bright red fringed with yellow, very double; Mars, dark velvety red, very free flowering; Perfecta, maroon shaded with lemon, very distinct variety; Wm. Rollinson, dark reddish crimson, splashed with orange, the freest flowering variety of all.

Correspondence.

The Lake Scenery of Central New York.

To the Editor of GARDEN AND FOREST :

Sir.—The policy which you have often advocated of establishing a state board of trustees empowered to acquire and hold for public use and enjoyment tracts of interesting scenery, suggests a means whereby a most valuable feature of the lake scenery in central New York might be preserved. The rocky gorges through which flow the tributaries from the surrounding hills into these lakes still retain much of their original beauty, although the regularity of the water-flow has doubtless been materially changed by the clearing off of trees about their sources, and the frequent inroads made upon those which border these ravines upon either side. In spring the water rushes down in full streams, so that strongly supported bridges are needed to withstand their power; but as the season

advances the channel becomes nearly or quite dry and in places exposed to the sunlight, while the more shaded portions are kept moist by springs along the hill-side, the waters of which filter through the soil and drip from the rocks. The timber in some instances has been removed entirely from the less precipitous slopes, which, if available, are cultivated; but where they have proved too steep or rocky for cultivation a new growth of trees is struggling to reoccupy the land.

From the summits of the hills that slope toward the lakes a very extensive view may be obtained, in which the trees that follow these water-courses are a most conspicuous and beautiful feature, comprising as they do a large variety of deciduous trees, interspersed with Pine, Hemlock and Red Cedar in considerable quantity, and the combination presents those inimitable shades of color which are only found in a wood of Nature's planting. These evergreens, growing down as they frequently do to the shore of the lake, are not less to be prized in the winter landscape.

Though holding, perhaps, a second place to the trees in importance, the loveliness seen by those only who penetrate these sequestered glens is surely worth preserving. The configuration of rock, as well as the verdure with which it and the soil are covered, vary so much in each one, that no matter how many of these glens we visit, each one has a charm as fresh as if no other one existed. Cascades are frequent, and the sound of falling water, either near or distant, makes constant music in almost all of these ravines. Ferns and Mosses follow the shade and moisture over rocks and hill-sides, growing out of crevices where no soil is visible. The little *Asplenium trichomanes* forms with the finer Mosses pretty mosaics on the rugged surfaces. The curious Walking Fern, *Asplenium rhizophyllum*, has a good footing in one locality, but is rare in others. As these and many other tender plants are now found only where shade and moisture are uninterrupted, it follows that if the timber is destroyed they must go with it, leaving bare rocks as a rule where now they are the exception.

Any intervention on the part of the public to stay the destruction of this beautiful as well as useful scenery would, of course, be unnecessary if the possessors of this natural inheritance realized its value; but as many of them do not, it is only by concerted effort on the part of those who do that any positive and hopeful step toward its preservation can be taken.

Klinger Lake, Mich.

Dorcas E. Collins.

The Trees of the City of Washington.

To the Editor of GARDEN AND FOREST :

Sir.—No city in the country is so well supplied with well-planted and neatly kept public grounds as the national capital. This is largely due to the fact that the planting of the streets and most of the parks is under one management, thus permitting unity of design and effective treatment. Among the points of interest to be noted in the management of these grounds are the following :

1. The removal within the past few years of most of the fences surrounding the parks.

2. The planting of entire streets with trees of one species. For example, Eleventh Street, for its entire length of two miles, is lined on both sides with Sycamores; Fourteenth Street with Soft Maples; Sixteenth Street with Tulip-trees; Massachusetts Avenue with Lindens.

3. Severe pruning of trees which have become overgrown. For the best street effect full-sized trees are in most cases too large. Heavy pruning may injure the vitality of a tree and shorten its life, but the advantage often justifies the process. The Sycamores on Eleventh Street, now six to twelve inches in diameter, were three years ago cut back to bare poles and mere stubs of branches. Now they are as perfectly formed and thrifty trees as can be found in the city. This season the Honey Locusts have been treated in the same manner, though less severely. This tree is too spreading in habit for the best effect as a street tree.

4. Prompt removal of trees which have proved unsuitable, or which have become unhealthy or hopelessly overgrown. This is a point often neglected on grounds under private management. Sentiment frequently resists with the utmost persistence changes which the best judgment requires.

5. Surrounding the bodies of trees on the leading streets with galvanized wire netting, a precaution rendered doubly necessary by the fact that hitching rings and posts are almost unknown, and that it is the custom here more than in ordinary commercial cities to restrain horses by a weight or leave them unhitched altogether.

If I were to note any omissions they would be, the failure to utilize to a sufficient extent the leading native trees of the

district, especially the Oaks, which occur in great abundance and variety; also to provide in the parks as well as on the streets for the landscape effect produced by massing trees of a single species under conditions permitting their full development. A grove of Oaks, Chestnuts, or almost any other kind of tree, in a commanding position, with an abundance of room, is a feature the production of which occasionally is worth the sacrifice of considerable temporary or local effect. Perhaps more of this will be sought in Washington in planning the new parks recently provided for on Rock Creek.

Washington, D. C.

A. A. Crozier.

Periodical Literature.

THE October number of the *Kew Bulletin of Useful Information* contains an article on cocoanut butter, a valuable edible fat prepared from the kernel of the cocoanut and recently introduced into commerce. It is a white, inodorless, almost tasteless fat, which solidifies at about sixty-five degrees Fahr., becoming above that temperature a pure white oil. Mr. Morris, the editor, says that "if cocoanut butter can be prepared, as is suggested, from the ordinary 'copra' or dried kernel of the cocoanut as shipped from tropical countries, there would be an almost unlimited supply of the raw material available from various parts of the world." According to Dr. Zerner, of the Royal Imperial and General Hospital in Vienna,

"The cocoanut butter, which, on account of its low melting point, is exported in tins, furnishes a pure white transparent mass of the consistence of lard without granular texture, which at a temperature of seventy-nine degrees Fahr. melts to a clear fluid and solidifies again at sixty-seven degrees Fahr. It has a slight agreeable smell, melts on the tongue, leaving a mild, but in no respect acrid taste behind it. In ether it dissolves completely. If the ether is evaporated over water and distilled water is added to the residue, the solution gives a neutral reaction. I have often repeated this test with cocoanut butter which had remained open for days (fourteen days), also with pharmaceutical preparations eight to fourteen days old, in the preparation of which cocoanut butter had been used. The cocoanut butter is therefore free from fatty acids, and even if left open for the space of eight to fourteen days does not turn rancid, with the exception of the top layer, which comes in contact with the air.

"With regard to its chemical composition, cocoanut butter differs from most other fats, and particularly butter, lard and margarin. In its fatty constituents and the amount of volatile fatty acids, it stands next to butter among solid fats.

"Cocoanut butter differs from all other vegetable and animal fats by its saponification degree (258.5 according to Rud. Benedikt in Vienna), and on account of this high saponification degree all adulteration is impossible.

"Artificial digestion tests seem to show that the cocoanut butter exercises no injurious influence whatever over digestion.

"The next point was to ascertain how the cocoanut butter stands with regard to micro-organisms. It is well known that in this respect milk butter is very far from perfect, as apart from the numerous germs, which, for the most part, are not pathogenic, that may be introduced during its preparation, and the microbes already present in the milk itself, this article of food affords an excellent nutrient fluid for a large number of micro-organisms.

"It follows that, although in any given case other ways and means of infection may be excluded, this may still take place through the agency of milk and butter. The possibility of a transfer to the human consumer of the Tubercle-bacillus, as well as of other micro-organisms, which have got into the milk from animals suffering from infectious diseases, is in the case of cocoanut butter, a vegetable fat, excluded from the first. Cocoanut butter has been proved by our investigations to be both free from germs and also to be a very bad nutrient medium for micro-organisms. Even when Agar-Agar or Ceylon Moss (*Gracilaria lichenoides*) was mixed with the cocoanut butter, and then allowed to remain open, the number of germs was found to be less than in Agar-Agar without the mixture of butter. One more experiment may be mentioned. If sterilized milk is added to cow butter and kept at a warm temperature the milk coagulates in twenty-four hours, proving the presence of bacteria in the butter. This coagulation does not take place if, instead of milk butter, cocoanut butter is added to the milk.

"From what has already been said the conclusion may safely be drawn that the cocoanut butter, from a chemical and bacteriological point of view, meets all the requirements of a food substance.

"Our further investigations were directed to ascertaining whether cocoanut butter was suitable to healthy and sick people alike. Through a period of four weeks we distributed food to 116 patients in the form of pastry, roast meats and farinaceous foods, in the preparation of which cocoanut butter was used in the place of fats.

"On account of this fat being almost free from water, one-quarter less may be taken, both in baking and cooking, than is generally used, if ordinary butter or lard is employed; and for the same reason it is necessary in making pastry to replace the twenty-five per cent. of water, which the cocoanut butter contains less than any other fat, by adding from seven to eight tablespoonfuls to about every pound of butter used.

"A little more salt must be added to the food, and the butter must always be heated before being used for cooking. Foods prepared in this way, as well as pastry, were always found to be eaten without any inconvenience whatever. The taste was undoubtedly pleasanter than in dishes prepared with animal fats. The statement of a colleague, Dr. H., is of particular importance in this respect. After recovering from disorder of the stomach he could not eat pastry without being afterward troubled with pyrosis and cardiac pain. He could eat pastry prepared with cocoanut butter almost without any inconvenience.

"The experiments with patients proved cocoanut butter to be an easily digested fat that causes no disorders in cases of impaired digestion. Of the 116 patients, amongst whom were individuals affected with every form of dyspepsia, not one complained of any discomfort or of any ill effect after the consumption of pastry prepared with cocoanut butter, though pastry, as a rule, is not an easily digested food on account of the fat. In three cases where the pastry was partaken of an hour after vomiting, there were no ill results noticeable; on the contrary, a fresh supply was desired by the patients.

"We arrive at the conclusion that a fat has been found in cocoanut butter which meets all hygienic requirements, and which is far superior to animal fat and butter, as well as to any of their other substitutes. Further, on account of its being easily digested, cocoanut butter is particularly well adapted for the use of patients suffering from impaired digestion."

Notes.

The largest Orange grove in the world will be planted this winter in the San Jacinto Valley, San Diego County, California. The largest grove at present is in Pomona and covers 400 acres. The new one will contain 700 acres of the best varieties.

Walpole used a pretty and epigrammatic expression in speaking of Kent, the "father of modern landscape-gardening." Dissatisfied with the formal style of gardening previously in vogue, "he leaped a fence," writes his biographer, "and saw that all nature was a garden."

Very many of the Horse-chestnut-trees which line the Prater and certain streets in the interior of Vienna bloomed profusely toward the end of last September. The phenomenon had often been noted there before on isolated trees, but is said never to have been so widespread as this year.

Freaks in fence-building are not uncommon in New England. Not many miles from New Bedford, for instance, is a solid fence with a curiously curved upper line and here and there a number painted upon it in white. On examination it proves to be built of the pew-doors from a dismantled church. And now we read in the *Times*, of Bath, Maine, an account of a man, attached to the life-saving station at Small Point, who has amassed enough of swords of the swordfish to build a picket fence forty feet in length.

The first Chrysanthemum exhibition held in Newport, Rhode Island, was open on the 11th, 12th and 13th of November. The attendance was poor, owing to unfavorable weather, but the display of flowers was satisfactory. The largest contributions came from the gardens of ex-Governor Wetmore and Mr. Louis Lorillard, but there were very creditable contributions also from Vice-President Morton, Mr. Fairman Rogers, Mrs. G. F. Jones, Mr. Cornelius Vanderbilt, Mr. D. B. Fearing and a number of others.

Among the highly successful Chrysanthemum exhibitions of the season was one held in Buffalo under the auspices of the florists' club of that city. Besides the plants and flowers exhibited by the city growers, Messrs. Pitcher & Manda, of New Jersey; Kimball, of Rochester; Dreer, of Philadelphia, and W. L. Scott, of Erie, Pennsylvania, contributed noteworthy

collections of Orchids and decorative plants. Some specimens of the Mrs. Alpheus Hardy were exceptionally robust and well grown, and a group of new Carnations of striking form and color were shown by Gustavus Schoenfeld, of Westfield, New York.

Mr. C. M. Weed, of the Ohio Experiment Station, in speaking of the Curculio which is destructive of Rhubarb, says that during the present year its life history has been traced, and it now appears that the insect hibernates as an adult, and in spring deposits its eggs in certain common species of Dock, especially Curly Dock—*Rumex crispus*. From the discovery of the breeding habits of this Curculio it seems evident that the best way to prevent its ravages is to destroy the Dock-plants on which it develops. If these are pulled up, roots and all, say late in June, before they have gone to seed, and burned, a great many of the insects will be destroyed.

Hundreds of thousands of plants and flowers are now on exhibition in Madison Square Garden. The display is not only remarkable as the collection of a single firm, the Messrs. Pitcher & Manda, but it would be classed as an admirable exhibition anywhere. Chrysanthemums are, of course, a leading feature, and although the season is so well advanced many first-class blooms are seen. The bank of Cypripediums in the centre of the Garden could not be duplicated by any establishment in the world, and the exhibition is rich in other Orchids, specimen Palms and Ferns. The immense space is well filled, and the plants are tastefully and effectively arranged.

The tomb of the poet John Boyle O'Reilly is to be marked in Holyhood Cemetery, Brookline, Massachusetts, by a giant boulder about twelve feet in diameter, which lies just as the glacier left it on the crest of a picturesque little hill. It would be well if monuments of this sort were more often used in our rural burial-grounds instead of the costly, ugly and obtrusive specimens of the stonecutter's art which are too commonly employed. Even if such a stone cannot be found in an appropriate place, it can easily be removed and so arranged with vines that will quickly drape it, that it will present a natural appearance. Nothing is needed to fit it for a monument except that a small space should be smoothed like a tablet to bear the inscription, as will be done in the case of Mr. O'Reilly's tomb. Apart from their harmonious and modest, yet dignified, effect, no monument is so imperishable as one of these which Nature herself has made.

The great game park which Mr. Austin Corbin has established near Newport, New Hampshire, and which contains 22,000 acres chiefly of mountain land, is being rapidly stocked with animals. Already some 250 head of buffalo, elk, moose, black-tail deer, white-tail deer, red deer, caribou, antelope, and wild boars from the Black Forest of Germany are roaming at large in the park, while contracts for as many more animals have been made with trappers at the west. Some of the species have already begun to breed, and the scheme promises results as satisfactory to the lover of great game as to those who are interested in any enterprise which involves the preservation of large tracts of beautiful country in their natural condition. It is said that Mr. Corbin does not intend to allow his animals to be hunted, and it will be some time before he must decide what shall be done with them when they have multiplied in excess of the capacity of the park to support them.

In an address before the Pennsylvania Horticultural Society Mr. John Thorpe stated that many forms of Chrysanthemums were undoubtedly introduced from Europe to America before the beginning of the present century, and that he had traced back some varieties as far as 1811, and, indeed, he exhibited a variety which had been cultivated in one family for more than sixty years. There are many kinds to be seen in Virginia that have been known there for over fifty years. They are nearly all Pompons, though some are of the Chinese sorts, as old Lilac, Golden Yellow and the Changeable White. He added that he had lately seen in a volume of the *Gardeners' Monthly* for 1860 an account of an exhibition thirty years ago in Philadelphia in which Chrysanthemum-plants of perfect shape and fifteen feet in circumference were shown. Some of the Pompons, like Madame Lafarge, Sacramento, Rosette and Napoleon, had between two and three thousand flowers expanded at once upon them.

The inhabitants of New York State seem at last to be awake to the necessity of preserving their forests. Together with the promising outlook of the scheme for forming a great state

park in the Adirondacks, we have to chronicle the fact that a movement has been started at Kingston for the establishment of a similar park in the Catskills, and that the matter, it is hoped, will be brought before the incoming Legislature. The state already owns 30,000 acres in the Catskill region, and it is probable that this amount will be increased by the Comptroller's tax-sale which will take place in December. Many private parks have within recent years been established in these mountains, and despite the fact that they were formed to accommodate colonies of summer visitors, the preservation of the forests has been helped, not hindered, by them. The amount of forest which is cleared for the building of houses is very small in comparison to that which must be preserved to perpetuate the charm of neighborhood and outlook upon which the value of the dwellings depends. Their owners have chosen the various sites for their picturesque beauty, and understand that this beauty must be kept as intact as possible. Nevertheless, there is room and need, here as well as in the Adirondacks, for the establishment of a state reservation.

On the occasion of a ball recently given in the club-house at Tuxedo Park the decoration of the ball-room was entrusted to an expert, who, nevertheless, is not a florist—Miss Stearns, of the Associated Artists of 115 East Twenty-third Street. The result proved that something might be done in the way of floral decoration which would lack the conventionality that so often marks such arrangements without falling into the heterogeneousness of amateur attempts. The room is very large and circular in shape, with fourteen windows alternating with fourteen columns which sustain the cornice. On one side is a stage where the musicians were to sit. This was decorated in harmony with the pretty woodland scene which formed the background, high Palms flanking the sides, while a row of lower Palms, mingled with Chrysanthemums, bordered the stage, and trailing Ivy fell over the front. Chrysanthemums were also intermixed with the taller Palms, in three shades of pink, making a charming effect as the electric light shone up over them from the foot-lights. This scheme was continued around the room by banking the window-recesses with Hemlock boughs and great sprays of white Chrysanthemums, the dark green foliage being carried up into the coves of the domed ceiling. The columns were covered with autumn foliage, Oak-leaves of a dark reddish bronze color forming the base, and being shaded gradually up into terra-cotta tones and finally into the yellow of Maple foliage. On this background Chrysanthemums were arranged, likewise in graded colors, beginning below with dark red blossoms and shading up to the capitals, which were encircled by masses of golden Grandiflorums. To obviate, however, an undue contrast between these red and yellow pillars and the pink and green of the stage, the two columns adjoining these were differently treated, being wound with Hemlock foliage interspersed with white Chrysanthemums—the same scheme of color chosen for the window recesses. The total effect of the beautiful room thus adorned was at once dignified and festal, and—an essential consideration in such cases—it made an excellent background for the gay dresses which filled it.

National Forest-Reservations.

ON the last day of the first session of the present Congress a bill was passed "to withhold from settlement, occupancy and sale, and to set apart as reserved forest-lands" the entire basin where the waters gather and through which they flow before they reach the Yosemite Valley. The boundaries designated in the bill include 1,500 square miles, and the Yosemite reservation is thus practically enlarged to thirty times its original extent. In the same bill two other reservations are set apart south of the Yosemite, which really add 150 square miles to the Tulare Park provided for in a bill passed earlier in the session. Besides these enactments, a bill to enlarge the Yellowstone Park passed the Senate, and comes before the House with no serious opposition beyond what is made by a corporation which seems to be lobbying for some exclusive privileges. There is little danger that Congress will rescue from desolation too large an area of mountain forests, and in a few years every one will wonder why our law-makers were so short-sighted as to permit the failure of Senator Edmunds' bill to establish a great reservation in northern Montana about the headwaters of the Flathead River and some of the tributaries of the Missouri, a region which contains some of the grandest scenery of the continent.

Of course, every year's delay makes such legislation more difficult, and as the unprotected forests are burned and the unprotected game is butchered much of the land now eligible will be hardly worth holding in reserve. The most thoughtful people of New Hampshire may well regret that the White Mountain forests were not held at their true value twenty-five years ago ; and it will cost the state of New York millions of dollars to save a remnant of the North Woods, although the entire wilderness might have been bought at a comparatively trifling expense when Horatio Seymour recommended such action. There is little hope that any considerable stretch of the primeval forests which still clothe many of the slopes and crests of the Appalachian Ranges from Virginia to the Big Smokies will be preserved to give our descendants an idea of their magnificent proportions and their unequalled variety.

In a few years, unless Congress continues the good work recently begun, the same lamentation must be taken up for the forests on the national domain which are so rapidly passing from under the control of the general Government.

If we assume that the recent action of Congress indicates a change of policy and that other "parks" and forests in our western mountains are to be reserved, some systematic scheme of administration will need to be devised. The attempts of governments, state and national, to protect what has been reserved have not proved up to this time conspicuously successful. When Congress refused to make any appropriation for the superintendence of the Yellowstone Park, this wonder-land was handed over to the control of an officer of the army with a troop of cavalry. Although this officer as acting superintendent could only exercise a limited and inadequate authority under the law, the presence of a disciplined force representing the power of the United States has proved the most efficient means of protection which has yet been tried. It is our belief that neither the national reservations nor the public forests will be safe until the United States army is actively engaged to protect them. It may well be that something in addition to the visible power of the Government in the presence of the army will be needed to secure the widest usefulness of these reservations. If so, it might be well to consider the advisability of some board of commissioners like the one proposed in Massachusetts to administer grants of forest-land, or of places of historic interest or natural beauty. There are men of leisure and cultivation in the country who would be glad to render such service gratuitously. Or the administration of all the reservations might be entrusted to some body of similar constitution to that of the Light-House Board, a body, for example, composed of army officers and men of recognized acquirements in forestry and such other subjects as would give weight to their counsel in the management of such a trust.

Attention is directed to these questions now, because the discussion of them cannot begin too soon. We are sure that the action of Congress in establishing these new reservations will be heartily commended throughout the country, and that further legislation in the same line would also be approved. It is to be hoped that the action of Congress in regard to the maintenance of these reservations, new and old, will be as wise as their recent legislation has been timely.

THE appointment of Mr. Frederick Law Olmsted as landscape-gardener to the committee having the Chicago "World's Fair" in charge, seems to promise that due regard will be paid to the disposition of the various buildings and their interdependence as parts of an organic whole. It was the masterly manner in which the buildings were grouped and surrounded by plantations which rendered the last Paris Exposition infinitely more impressive and interesting than any of its predecessors in any country. There, however, the fact that the site included broad slopes descending to the river on one side, and from the river on the other, and that on the upper slope the fine terraces of the Trocadero Palace already existed, facilitated the designers' work. At Chicago a perfectly level site must be dealt with, although, indeed, it has the advantage of a magnificent lake front and of wide park areas already planted. Considering the character of this site there is food for reflection in the following paragraph, which we quote from the *American Architect and Building News* : "We have always thought that the future Chicago buildings might, with a little judicious expenditure for concrete terraces and similar works, be made much more imposing than those of any previous exhibition. There is likely to be plenty of room at Chicago, as there was at Philadelphia, and this makes it all the more advisable, as an artistic matter, to connect the buildings by terraces, balustrades, colonnades or something of the kind, so as to avoid the impression suggested at Philadelphia, that the various structures had been prepared by the inhabitants of different planets and rained down at random on Fairmount Park."

City House-Gardening.

THE opportunities for gardening available to the average city-dweller are so circumscribed that he is apt to consider them hardly worth using. Garden space is usually limited to a few square feet between the house and the sidewalk, or to the back-yard, and to the windows and possibly the roof. Attempts at cultivation are confined as a rule to the handkerchief-like bit of ground in front, where the grass is sometimes kept in good condition by the residents of a whole block, who unite in engaging a man with a lawn-mower to maintain it for the season. If anything is done beyond this, efforts are usually confined to the planting of a few *Geraniums* or a solitary shrub, which may blossom for a few days in this or that part of the season and show little life or beauty the rest of the year.

A distinctive advance, however, has been made in some of our cities of late years. One evidence of this is the universal favor which the Japan Creeper (*Ampelopsis tricuspidata*) has found. Its use on the house-fronts is a great relief to our city streets, and in most of them is an improvement upon shade trees, which are out of place in a closely built urban thoroughfare that is not of exceptional width. In certain quarters of some cities good examples of house-front gardening have proven so infectious that even a suburban resident, accustomed to more ample spaces, finds delight in wandering through them and noting the diverse effects. These are often charming, and are carried through the season from early spring to late autumn. In a sunny exposure the coming of the spring will often be manifest far in advance of the season out in the country close by, and the grass of the little space will be gay with *Snowdrops*, *Crocuses*, *Hyacinths*, *Tulips* and *Narcissus*, in succession, while the scent of the sweet *Violet* pervades the air. Through the summer the doorsteps will be bordered with pots of *Hydrangeas* and a variety of other flowering plants, with perhaps *Bamboos* and other tropical plants in tubs. On the house-front a variety of surface is presented, perhaps, by the Japanese *Ampelopsis*, irregularly diversified with *Virginia Creeper* and *Wistaria*, and possibly inlaid with the dark glossiness of the English Ivy, which occasionally flourishes even in our more northerly cities. All this luxuriant greenery contrasts with the background of rich red brick, or of the always harmonious hues of stone, be they brown, buff or gray. Then possibly the windows may contain masses of bloom in boxes, and the doorway likewise be crested with a floral glory. In the autumn the gorgeousness of the creepers as their leaves turn vies with the country-side in splendor, and, as the tender growths on the doorsteps are retired, their places are taken by the *Chrysanthemum*, and the season expires in a prismatic array of color.

Even in a tenement street there may be encountered an occasional oasis of bright blossoms in some window—often a token that Germans or Italians inhabit the place. In Boston the action of the Massachusetts Horticultural Society has multiplied these sights to a remarkable degree by the encouragement it gives to children for window-gardening, and many eyes and hearts are thereby gladdened.

The opportunities offered by the back-yard are almost entirely neglected, and that locality is usually a sorry place in our cities. We should go to school to the Japanese to learn what is possible here. In that important and extremely interesting work, "Japanese Homes and Their Surroundings," Professor Edward S. Morse devotes a chapter to the garden. As an illustration of how the smallest areas of ground are utilized for gardens and garden effects, he recalls an experience in a cheap inn: "The immediate surroundings indicated poverty, the house itself being poorly furnished, the mats hard and uneven, and the attendants very cheaply dressed. In the room where our meal was served there was a circular window, through which could be seen a curious stone lantern and a Pine-tree, the branches of which stretched across the opening, while beyond a fine view of some high mountains was to be had. From where we sat on the mats there were all the evidences of a fine garden outside; and wondering how so poor a house could sustain so fine a garden, I went to the window to investigate. What was my surprise to find that the extent of ground from which the lantern and the Pine-tree sprung was just three feet in width! Then came a low board fence, and beyond this there stretched the rice-fields of a neighboring farmer. At home such a narrow strip of land would in all likelihood have been the receptacle for broken glass and tin cans, and a thoroughfare for erratic cats; here, however, everything was clean and neat—and this narrow plot of ground, good for no other purpose, had been utilized solely for the benefit of the room within."

Again he says: "The Japanese have brought their garden arts to such perfection that a plot of ground ten feet square is capable of being exquisitely beautified by their methods. . . . With cleanliness, simplicity, a few little evergreen shrubs, one or two little clusters of flowers, a rustic fence projecting from the side of the house, a quaintly shaped flower-pot or two, containing a few choice plants, the simplest form of garden is attained. So much do the Japanese admire gardens and garden effects that their smallest strips of ground are utilized for this purpose. In the crowded city, among the poorest houses, one often sees, in the corner of a little earth-area that comes between the sill and the raised floor, a miniature garden made in some shallow box, or even on the ground itself."

I lately noted a charming back-yard effect while passing a house that was undergoing reconstruction for business purposes. The front and rear of the first story had been removed, so that the large rectangular opening at the further end seemed like a framed picture in which were revealed gracefully disposed masses of vines and shrubs with some picturesque architecture for a background. But such glimpses are rare. The back-yard of any city house is capable of being made a delightful spot instead of the desolate space that it now almost universally is. Even the absence of full sunlight is no insurmountable obstacle, for *Ferns* and *Mosses* will grow luxuriantly in a place that is always shady, as well as many beautiful shrubs and plants, including the shadow-loving *Begonias* and *Fuchsias*, whose abundant masses of brilliant flowers, with their variety of coloring, show most luminously against the cool green semi-obscure of such a place.

Roof-gardens have a great attractiveness in a city, and we occasionally hear of some very delightful places of the kind. They have the advantage of light and air, and often of a beautiful view, with space for awnings, hammocks, easy chairs and other comforts that go far to reconcile the stay-at-home to his lot of life in town for the summer.

Were it not that so many families leave town so early in the season and do not return until summer has passed, we should see more attention paid to city-house gardening. But, as it is, there are thousands of even well-to-do families some of whose members stay in the city the greater part of the summer, and who would be well repaid for taking some trouble in this direction.

A Vase of *Chrysanthemums*.

THE recent exhibitions at Boston and Philadelphia proved by many good examples the decorative value of *Chrysanthemums* cut with long stems and loosely arranged in vases. The best varieties for this purpose are not those considered of the highest merit according to exhibition standards. The flowers should not be too large, and should excel in breadth rather than depth. They should have abundant foliage, so that no other contrast to the flower is needed than a good background. If only one variety is used the effect will generally be stronger than if different forms and colors are employed together. Perhaps, too, it is desirable to emphasize the special qualities of this favorite flower, which are a profusion of bloom and a mass of color, and in that case we should use as many flowers as possible, without giving the appearance anything like crowding.

Our illustration, page 587, shows a vase of the flowers of the *Chrysanthemum* Ada Spaulding. The flowers of this variety have great substance, and when well grown are very deep. A group of them on longer stems and standing rather more erect than those in the illustration would probably have a bolder and more characteristic effect. The *Ada Spaulding* has gained a high rank among the newer kinds of this type. The plants have a vigorous habit, the flowers are massive, well imbricated and usually colored in a pleasing way. The flowers here shown are from strong plants, as is evident from their healthy foliage, although they are not so finely imbricated as many exhibition specimens which we have seen. The illustration, however, is not meant to display the special qualities of this variety, but to indicate one of the best ways in which *Chrysanthemums* can be employed for in-door decoration. It is taken from a photograph of one of the vases which were exhibited at Boston by Galvin Brothers, and which were characterized in our report as one of the noteworthy features of the show. The flowers were grown by Mr. S. J. Colman.

The simple, uncombined landscape, if wrought out with due attention to the ideal beauty of the features it includes, will always be most powerful in its appeal to the heart.

Ruskin.

Notes on the Distribution of Some Kansas Trees.— I. The Red Cedar (*Juniperus Virginiana*).

A STUDY of the distribution of trees in Kansas furnishes many facts of interest to the student of forestry. On the east the dense forest growth of Arkansas and southern Missouri extends but a short distance into the state. Of about seventy species of trees with which Kansas is credited, the majority can be found in the eastern tier of counties. Along the line of the hundredth meridian the number of species is reduced to a dozen, of which not more than two or three will reach the Colorado line. This gradual thinning out, first of species and at length of entire genera, under the more trying conditions encountered as we move further west, will afford suggestions to one wishing to select the most hardy trees for the planting of timber-claims or shelter-belts in the prairie region.

A peculiar feature of timber growth in the western part of Kansas is that the trees on the main stream may entirely disappear, while upon many of its tributaries, back but a few miles, quite a heavy growth may be found where there is not water enough in the stream to float a canoe. The only explanation that I have seen offered for this was that the beaver had kept down the young trees on the larger stream, where there was a sufficient volume of water for them to work. Perhaps we should add to this the work of fires, floods and grinding ice, which could readily be carried over the low sandy banks of these streams. The nature of the soil may have been the most important factor of all, for the bottom lands along these treeless streams are very sandy, and the low banks slope so easily to the water that where the grass is dense enough the fire could sweep to the water's edge. Superficial observers of Kansas timber have often been misled by this lack of trees along the Saline, Smoky Hill and Arkansas Rivers, and supposed that they had passed west of the timber limit of the state.

The commonly planted Cottonwood, though one of the most westerly trees in distribution, is a moisture-loving tree and is seldom found growing naturally far from streams or springs. It is not surprising that of the many thousands of these trees planted on high prairie the majority die after a few years of encouraging growth. It is to trees which are found growing on more dry and elevated locations that we must look for the greatest success in maintaining forest-conditions on the uplands. The Hackberry (*Celtis occidentalis*), for example, is often found along western streams growing upon the face of some rocky bluff where only the most scanty supply of moisture can reach its roots. The farmers in these localities report it as being one of the most successful trees that they can use in dry situations.

The Red Cedar is found in Kansas in a much more western habitat than has usually been assigned to it, and often growing in such dry and sterile places that it would seem as if it could thrive anywhere if once its roots obtained a hold upon the soil. Throughout the carboniferous formation of the south-eastern part of the state this tree is frequently found, usually growing along rocky banks and rugged bluffs overlooking the streams, and by the very barrenness of the spot fully protected from the approach of fire. Here they give a picturesque touch to the landscape which is very pleasing, especially during the winter months. West of the lower Republican Valley they disappear, only to be found again in isolated stations much farther west. In the eastern part of Trego County the geological formation is a soft, chalky limestone; and on the south side of the Smoky Hill River this rises in considerable bluffs. In Ranges 22 and 23 west, or within about twelve miles of the 100th meridian, a group of these chalk hills is known as Cedar Bluff, and at one time their abrupt northern slopes were covered with a fine growth of Red Cedar over an extent of several hundred acres. A small tributary from the south, entering the river at this point, is locally known as Page Creek. Near its head is another chalk bluff, which was once equally well timbered. With the settlement of the prairies these trees were cut and hauled away to furnish ridge-logs and rafters for the sod-houses, while every branch, and even the stumps and roots in many cases, were used as kindlings for the cow-chip fires. The Page Creek Cedars were almost exterminated in this way, and all the more valuable growth on Cedar Bluffs was taken; but here young trees are coming in to some extent, and in time, if protected, the growth may be restored.

Scattering groups of Cedars are remembered by the old settlers along the upper Solomon River growing in this same chalky formation. Somewhere on the upper Republican River, in early times, a large raft of these trees was cut and

floated down the stream to the lower part of Clay County, where it came to grief on a sand-bar, and was distributed among the settlers. The presence of these isolated groves of Cedar so far west would seem to indicate that the climate is not so arid that they could not be grown artificially on a much more extensive scale. These trees were all in such situations as to be secure from fires and from the rush of thousands of sharp hoofs when this country was the pasture land of the buffalo.

On account of the expense of procuring young trees and the difficulty in making them live through the summer drought following their planting, but few Cedars have been set out, except for ornament or as an occasional shelter belt. So far as they have been tried near their native stations they have been found very successful when once established. Accurate measurements of growth for any of the more western specimens are not in my possession, but trees can be found around Manhattan twenty years old which are eight to twelve inches in diameter at the ground and twenty to twenty-five feet high. Up to about fifteen or twenty years old, if not too crowded, they retain their limbs to the ground, and form a beautiful spire-like top. Beyond this age the lower branches die and the top becomes more round or irregular. An old specimen with grotesquely distorted trunk and gnarled and twisted branches is occasionally found growing from a cleft of a rocky ledge, where it is very picturesque.

It is to be hoped that the experiment may soon be tried of planting considerable tracts of these trees on high prairie and rocky land. As it is too expensive an enterprise for the average homesteader to undertake, state or government aid should be given in the matter. Those railroad companies that have to meet the heavy expense of keeping up miles of snow-fence along their lines would do well to try the Red Cedar on a small scale, and might find that a living wall of evergreens would be a more effective snow trap than a board fence, and maintained at a fraction of the cost. The comparative beauty of the two as seen from the train need not be dwelt upon.

The valuable suggestion contained in a recent editorial of GARDEN AND FOREST on the Improvement of Trees would doubtless apply well in this state, and seedlings grown from these native acclimated Cedars of the far west might be expected to endure the drying summer winds of the prairies better than stock derived from eastern forests.

Kansas Agricultural College.

The Cranberry Scald.

THE last crop report of the Secretary of the American Cranberry Association states that the present harvest is the smallest in New Jersey since 1884, and the Cranberry crop is twenty-two per cent. less than that of last year. The primary cause of this falling off in the yield is the trouble so well known as the "scald." I have made some study of this serious disease during the past two years, and hope that some light can be thrown upon this subject which may lead to improved bog management and at least to a partial mitigation of the trouble.

The disease makes its appearance in the fruit when it is about half grown, and may be detected as soft spots, quite small at first, but usually extending throughout the berry, when it takes on the appearance of one that has been partly cooked, although the skin remains unbroken. The skin being tough, the berry hangs as a collapsed cornelian bag for several weeks, when it finally falls to the ground. It is, however, not uncommon to find many scalded berries upon the vines in early spring. Frequently the berry remains half rotten, with a distinct line between the healthy and decayed portion, as shown in Fig. 75. After a time dark patches form beneath the skin, and pimples make their appearance upon the surface of the decayed part, as indicated in the engraving.

Fig. 75.—A Berry Partly Scalded.

When a diseased berry is studied with a compound microscope, the soft tissue is found to contain a great abundance of threads, which are no part of the substance of the healthy berry. The pustules upon the skin are made up of aggregations of these threads, in which a cavity forms as a small pit or cup. A section of one of these pits is shown very highly magnified in Fig. 76, and the internal structure is made plain. It consists of a multitude of fine threads, forming the wall of the cavity, with the inner surface lined with small projecting threads that bear minute spores upon their tips, and falling away escape through a slit or opening in the pustule.

All of this filamentous portion above described is a Fungus that is parasitic upon the cranberry, and feeding upon its

tissue induces decay, and finally produces a worthless, rotten berry.

An examination of other portions of plants bearing scalded berries showed that the same Fungus penetrates all parts of

Fig. 76.—Section of a Pustule.

the plant. Such infested plants have a half dead appearance, the leaves turn brown prematurely and readily drop from the vines. A leaf half affected with the Scald Fungus is shown in Fig. 77. The upper portion had turned brown, and upon its surface are many pimples similar to those already noticed upon the leaves. These pustules appear under the microscope to be practically the same as those on the berry.

Fig. 77.—A Leaf Half Scalded.

A study of the stem revealed the presence of the threads of the Fungus, and they were traced down to the root and into the soil. It is thus seen that the whole vine is infested and the infection is not confined to the berries. Deeply seated as the trouble is found to be, it is evident that any application of a fungicide to the berries could scarcely prove effective. Here is a case when the bog itself appears to be infested, and this is difficult to reach with remedies.

It is a fact obtained by an extended correspondence with Massachusetts cranberry-growers that the scald is with them only little known and not particularly damaging. The method of making the bog is quite different on Cape Cod from that in New Jersey. There sanding is considered a requisite, and the bogs are kept clean of weeds; but in New Jersey sanding is not practiced, and grass and weeds are not uncommon.

The great difference noted may have much to do with the prevalence of the scald in the last named state. While there are differences of temperature, rain-fall, etc., they are not great enough to warrant the assigning of meteorological conditions as those which control the scald.

It seems safe to assert that the soil conditions have the most to do with the development of the trouble, and in so far as these are subject to modification the scald is a subject for future control, but to what extent remains to be determined. It is suggested that if possible the soil conditions prevailing in Massachusetts be made those for New Jersey. Upon some scalded bogs it may be impracticable to do anything; sanding may be out of the question, and there may be a poor water supply, or it is not under control. There should be a healthy bog soil, not constantly water soaked and "sour."

The experiments during the present year with various chemicals applied to the vines and to the soil have not produced the desired results. It is predicted that the best results will come from experiments along the line of bog sanitation—that is, better water control and the provision for healthier conditions for the roots of the plants. Decaying vegetation and stagnant water are two of the probable conditions for the development of the scald.

New or Little Known Plants.

New Orchids.

SOBRALIA LOWII, Rolfe, is a dwarf and pretty little species, introduced from New Granada by Messrs. Hugh Low & Co., of Clapton. It grows from about twelve to eighteen inches high, and the flowers, which are freely produced, are of a uniform bright purple shade. It is allied to *S. sessilis* and *S. decora*.—*Gardeners' Chronicle*, October 4th, p. 378.

SOBRALIA WILSONIANA, Rolfe, is a fine species, introduced from Central America, with *S. leucoantha*, by Messrs. F. Sander & Co., of St. Albans. It flowered in the collection of A. Wilson, Esq., of Westbrook, Sheffield. It is apparently allied to *S. Warszewiczii*, and has the habit and stature of *S. leucoantha*. The sepals and petals are four and a quarter inches long, white, suffused with pale rose, while the lip is

rosy pink in front, paler behind, and with the disc and throat bright yellow.—*Gardeners' Chronicle*, October 4th, p. 378.

MASDEVALLIA × *MEASURESIANA*, Rolfe, is a very pretty little hybrid, raised by Messrs. F. Sander & Co., of St. Albans, from *M. tovarensis*, fertilized with the pollen of *M. amabilis*. It resembles the pollen parent in habit and in the terete peduncles, but in the shape and color of the flower it approaches nearer the characters of the seed-bearer. The perianth is white, with lilac nerves and margin, and darker tails.—*Gardeners' Chronicle*, October 4th, p. 379.

CYPRIPEDIUM × *H. BALLANTINE* is a neat and pretty hybrid raised in the establishment of Messrs. James Veitch & Sons by Mr. Seden from *C. purpuratum* fertilized with the pollen of *C. Fairieanum*. It is quite intermediate in character, rather inclining to *C. purpuratum* in shape, with the transverse reticulations of *C. Fairieanum* in addition.—*Gardeners' Chronicle*, October 11th, p. 408.

CATTLEYA AUREA IMSCHOFTIANA is a charming variety with pure white sepals and petals, and flowers somewhat smaller than usual. It was exhibited by Baron Schröder at a meeting of the Royal Horticultural Society on October 14th, when it was awarded a first-class certificate.—*Gardeners' Chronicle*, October 18th, p. 447.

CATTLEYA AUREA LINDENI is a beautiful variety with deep yellow sepals and petals and deep brown lip. It was exhibited by Messrs. Linden, L'Horticulture Internationale, Brussels, at a meeting of the Royal Horticultural Society on October 14th.—*Gardeners' Chronicle*, October 18th, p. 447.

CATTLEYA WAROCQUEANA FLAMMEA is a beautiful variety with rosy carmine flowers tinged with lilac, and the front lobe of the lip with a central crimson blotch. It was exhibited by Messrs. Linden at a meeting of the Royal Horticultural Society on October 14th, when it was awarded a first-class certificate.—*Gardeners' Chronicle*, October 18th, p. 447.

CATTLEYA WAROCQUEANA AMETHYSTINA is another very richly colored variety; the flowers of a deep rosy lilac, and the lip of a deeper shade, with narrow, paler margin. It was exhibited by Messrs. Linden with the preceding, and, like it, was awarded a first-class certificate.—*Gardeners' Chronicle*, October 18th, p. 447.

CATTLEYA DU BUYSSONIANA is a very pretty form of *C. granulosa*, with pale yellow sepals and petals, and the lip with crimson rose median lobe and paler side lobes. It was exhibited by Messrs. Linden with the preceding, when it received an award of merit.—*Gardeners' Chronicle*, October 18th, p. 447.

CATASETUM BUNGEROTHII, VAR. *RANDII*, is a beautiful yellow variety, which was exhibited by Messrs. Linden at a meeting of the Royal Horticultural Society on October 14th, and to which an award of merit was given.—*Gardeners' Chronicle*, October 18th, p. 447.

Plant Notes.

Some Recent Portraits.

Aristolochia longicaudata is well figured in the *Gardeners' Chronicle* of November 1st from a specimen brought to England from Demerara by Mr. Todd and cultivated by him. The flowers are cream colored, with purple, vein-like markings, the funnel-shaped throat at the top of the distended portion of the tube being velvety purple, covered with coarse white hairs with swollen bases, the points directed downward toward the bottom of the flower, where is placed the column of the stamens united with the styles. *Aristolochia longicaudata* belongs to the section of the genus in which the flowers are characterized by the solitary lip, which, in this case, is prolonged into a very long margined tail.

The colored plate in *The Garden* of London of the same date is devoted to an exquisite representation of *Benthamia fragifera*, the Indian representative of the Flowering Dogwoods of North America, the genus *Benthamia* being now joined by some authors to *Cornus*. We read that

"Where it will survive the winter without injury, and occupies an isolated position so as to allow of its full development, this native of Nepaul forms quite a tree, but with the character of a large shrub, the branches being numerous and wide-spreading, while they are plentifully clothed with oblong-shaped leaves of a rather distinct lighuish green tint. In some winters the foliage is almost evergreen, while in the case of an unusually severe one the greater part of it quickly drops. The flowers, which, in an established specimen, are usually borne in great profusion, are, as a rule, at their best during July and August. The reddish tinge which suffuses the major portion of the inflorescence is not nearly so pronounced when the

flowers are first expanded as it is after they have been open a few days. The blossoms, however, are but one part of its beauty, as the fruits of the *Benthamia* are wonderfully showy when ripe. They grow as large as a good sized strawberry, which they greatly resemble. When ripe, these berries are of a reddish hue, and though they usually ripen about October, they frequently remain on the trees throughout the winter."

In Cornwall and in the south of Ireland this plant seems to be at home, growing to a large size and flowering abundantly every year. It is little seen in less favored regions of Europe, and very probably has never been tried in America, although it would probably succeed in our southern states. There is a second species, *Benthamia Japonica* (*Cornus Kousa*), a smaller plant, with less showy flowers and fruit. This was introduced into American gardens many years ago, and has produced flowers at the Parsons' nursery in Flushing. As a purely ornamental plant, however, it has little to recommend it except its rarity over our common Flowering Dogwood of the east, *Cornus florida*.

Ipomœa ternata is represented at Kew by three most distinct varieties—namely, that known in gardens as *I. Horsfallia*, a second sometimes called *I. Briggsii* or Lady Briggs, and the third the type which was introduced a few years ago as *I. Thompsoniana*. The first of this trio is well known as one of the best of stove flowering climbers. Taken altogether, however, I think *I. Briggsii* is a more useful plant, on account of its freer, more elegant habit, and the profusion of its rosy crimson flowers in November. It is easily propagated from cuttings, and it will grow well with ordinary treatment. In the Palm House and also in the Victoria House at Kew it covers a large space against the roof, and its numerous shoots, which hang down several yards, are wreathed with flowers. The third variety is pure white, and, although larger than the other two, it is much less effective.

Lapeyrousia grandiflora is a hardy, autumn-flowering bulbous plant of considerable promise. In habit and foliage it resembles *Crocus*, grows about a foot in height and produces racemose scapes of flowers which are each fully two inches across. The segments are three-eighths of an inch wide and colored bright crimson, the three lower ones having a deep maroon blotch at the base. The behavior of the bulbs is the same as in *Crocus*, so that in time the plants should become common. *L. grandiflora* was introduced by means of seeds sent from Delagoa Bay to Kew in 1883. A figure of it (a poor one) was published in the *Botanical Magazine*, t. 6924. Last year a few of the bulbs were planted in a bed on one of the lawns at Kew and left out all winter. They have multiplied tenfold and flowered freely this autumn.

CHRYSANTHEMUMS.—The exhibition held by the National Chrysanthemum Society has been as great a success as circumstances would permit. The collections of plants and cut blooms, the conferences and the crowds which were attracted by them were successes. The chief drawback was the utter unfitness of the Aquarium as an exhibition hall for plants and flowers, and the consequent absence of anything like an effective display. In a proper hall the vast collections of flowers, many of them magnificent examples of culture, and the large groups of well flowered plants, would have presented a floral picture such as has probably never been seen before. The excitement of competition centred in the Centenary Class for cut blooms, twenty-four Japanese and twenty-four incurved varieties, the prizes, of which there were five, being from £25 to £5. First honors were awarded to a magnificent collection of blooms shown by Messrs. Drover, of Farnham. Old Chrysanthemum fanciers declared this to be the most superb collection of flowers ever seen. Almost every flower was a picture in finish, color and size. I give the names of the sorts included in this collection. Incurved: Lord Alcester, Queen of England, Golden Empress, Beauty, Prince Alfred, Princess of Teck, Mrs. Heale, C. Gibson, Mrs. Coleman, Alfred Salter, Lady Hardinge, Mrs. N. Davis, Emily Dale, Princess of Wales, Alfred Lynne, John Doughty, Violet Tomlin, Lady Dorothy, Empress of India, Empress Eugénie, Mrs. W. Shipman, Nil Desperandum, Jeanne d'Arc, Miss M. A. Haggas. Japanese: Madame Bacco, Ralph Brocklebank, Avalanche, E. Molyneux, Comte de Germigny, Stanstead White, Etoile de Lyon, Sunflower, Mrs. C. H. Clarke, Pelican, Baronne de Prailly, Mrs. C.

H. Wheeler, Mrs. A. Hardy, M. Bernard, Criterion, Jeanne Délaux, Boule d'Or, Mrs. F. Jameson, E. A. Carrière, Lady T. Lawrence, Sarah Owen, Meg Merriles, Condor and Gloriosum.

Almost every one of the sorts here named occurred frequently in other stands and collections. The first-rate kinds, which were well shown, in addition to the above, were—Japanese: Mrs. H. Cannell, Val d'Andorre, Maiden's Blush, Fair Maid of Guernsey and Album Fimbriatum. Incurved: Lord Wolseley, Mr. Brunless, Mrs. Heale, Hero of Stoke Newington and Barbara.

Tastes differ in regard to the beauty of different Chrysanthemums; my own taste places Edwin Molyneux first among the Japanese, and the old Queen of England first among the incurved.

Of other classes there were excellent examples shown, the reflexed being represented by King of Crimson, Cullingfordii, Cloth of Gold and Pink Christine amongst others. The Japanese Anemones included fine examples of Mademoiselle Cabrol, Madame Blanche, Sabine, Dame Nelson and Fabian de Mediana. Pompons were not abundantly shown, but such kinds as President, Rubrum, Perfection and Elise Dordan were good. There are evidences of a growing preference for size in the flowers of this section, which if not checked will result in their being improved out of all character. Their small, compact, button-like flowers are their peculiar attraction.

Plants were exceptionally good for the south of England, Mr. G. Stevens, of Putney, winning first honors for six specimens which would have done credit to a show in Liverpool or Manchester. Trained Standards were also splendidly shown. Untrained plants were, however, very weak, and it is evident that this style does not as yet meet with much favor amongst first-rate growers. While this exhibition revealed general progress in cultivation and considerable growth in the interest shown by the general public in Chrysanthemums, it did not give us anything startling in the way of new kinds or new methods of cultivation.

The following new plants obtained certificates at the last meeting of the Royal Horticultural Society:

CHRYSANTHEMUM ARTHUR WOOD (Japanese); large, rich chestnut brown, tipped with gold. (Cannell.)

CYPRIPEDIUM ANTIGONE × (*C. niveum* and *C. Lawrencianum*), a beautiful addition to hybrid Orchids. The flower is large, rose colored, with a few streaks and dots of a darker color. (Messrs. Veitch.)

C. DORIS × (*C. venustum* and *C. Stonei*).—Large flowered, but unattractive in color, being a mixture of green and dull brown. (Norman Cookson.)

C. EYERMANNIANUM × (*C. barbatum* and *C. Spicerianum*), combines the characters of the two parents, but is not an improvement upon either. (Sander & Co.)

C. CLEOLA × (*C. reticulatum* and *C. Schlimi*).—A promising plant, distinct and pretty in the colors of its flowers; the dorsal sepal is pale yellow, the petals cream colored and the lip white tinted with rose. (Messrs. Veitch.)

ODONTOGLOSSUM DUVIVIERIANUM.—A yellow tinted variety of *O. cordatum*. (M. Linden.)

VACCINIUM CORYMBOSUM, shown as *V. Pennsylvanicum*. The color of the leaves in autumn is a rich orange-red. In England this shrub is scarcely known, although at Kew and apparently in Mr. Waterer's nursery at Knap Hill it is exceedingly ornamental in November.

QUERCUS TINCTORIA, also shown by Mr. Waterer as the Knap Hill Scarlet Oak. Until the leaves fell the trees of this and of many other Oaks at Kew were exceptionally rich in color this autumn. Both the *Vaccinium* and this Oak were certificated on account of their ornamental foliage.

PRIMULA IMPERIALIS.—The true plant of this name is now in cultivation at Kew, where it has been raised from seeds imported from Java, on the highest mountain of which island this gigantic species was met with by Wallace, and described in his delightful book, "The Malay Archipelago." This *Primula* has leaves eighteen inches long and nearly six inches wide, while its erect flower-spike attains a height of five feet, the flowers being in whorls as in *P. Japonica*. About eight years ago an allied plant, or possibly a geographical form of this Javanese giant, was introduced from the Himalayas and flowered at Kew. A figure of it was published in the *Botanical Magazine* under the name of *P. prolifera*, the name *P. imperialis* being there quoted as a synonym. There is, however, a marked difference between the form and texture of the foliage of the Javanese and Himalayan plants, as well as that of dimensions, so that, for horticultural convenience at any rate, we may retain the name *Imperialis* for the Javanese plant. Next year, when probably the plants at Kew will produce flowers, we shall be in a better position to speak of their value in

gardens. The Himalayan plant finds little favor owing to the smallness of the flowers and their dull yellow color.

CHINESE PRIMULAS were the subject of a lecture by Mr. Arthur Sutton at a recent meeting of the Royal Horticultural Society. The well known firm of seed merchants, of which Mr. A. Sutton is a member, has for many years possessed a very superior "strain" of Primulas, obtained, I believe, mainly by themselves through crossing and selection. *P. Sinensis* was introduced into England from Chinese gardens about seventy years ago. As then introduced it was much superior to the wild type, having been improved by Chinese cultivators, with whom it had long been a favorite garden plant. The type we have been made acquainted with only recently through the collectors, the Abbé Delavay and Dr. Henry, whose specimens, collected in central and northern China, are now in the Kew Herbarium. The difference between the type as represented by these specimens and the best of the "strain" in cultivation in England is almost as great as the difference between the wild Chrysanthemum of China and its progeny as represented in gardens to-day. What is considered by Dr. Masters to be a very near approach to the wild Chinese Primula is now in cultivation in a garden in the Isle of Wight, where it was raised from seeds collected in China. I saw these plants in flower a few weeks ago; the flowers were small and pale lilac in color. The leaves, however, were much more interesting than the flowers, as when rubbed they emitted a strong agreeable odor. Messrs. Sutton have secured plants of this scented leaved variety. We may, therefore, look forward to possessing a strain of Chinese Primulas with fragrant leaves and large flowers.

Hitherto no one has succeeded in crossing *P. Sinensis* with any other species, or, rather, to be accurate, no one has flowered such a cross. I have seen seedlings which were undoubtedly hybrids between *P. Sinensis* and a Himalayan species, and which go to prove that such a cross is possible. Chinese plants are attracting more than ordinary attention in England at the present time, the result of Dr. Henry's and others' revelations of the floral riches of China which had not hitherto been dreamt of. At Kew there are seedlings of some of Dr. Henry's discoveries, and amongst them are plants of considerable promise.

LILIUM HENRYI.—I have only lately mentioned this new Lily as having flowered at Kew, but I refer to it again for the purpose of placing upon record a few facts recently communicated to me by Dr. Henry. It grows, he says, at higher elevations than *L. longiflorum*, and is therefore at least as hardy as that species. In Mr. Baker's description of *L. Henryi*, made from dried specimens, the umbel is said to contain eight flowers. Dr. Henry, however, says that thirty or more flowers are not uncommon on one stem. He also says that the stem attains a height of six or seven feet and that the bulbs are twice as large as a man's fist. From these particulars it is evident that in *L. Henryi* we have a plant of more than ordinary interest horticulturally. So far the bulbs at Kew have grown satisfactorily in an open border. They were very small and weak when received from China, so that the three-flowered stems produced by several this year may be taken as indicating a promising character for floriferousness.

Kew.

Fern Notes.

MANY very pretty and useful Ferns are found among the Aspleniums or Spleenworts, and most of them being of moderate growth are well adapted for small collections. This is a very extensive genus, and seems to have representatives in almost all parts of the globe. Of the exotic species, and among the smaller growers, *A. alatum* deserves prominence, its pinnate fronds being about a foot in length and light green in color, and as the plant gains strength the fronds are frequently proliferous near the apex. When properly grown *A. alatum* is a very attractive Fern, but as slugs seem to have a decided liking for the young fronds of this species, some watchfulness must be exercised in order to secure perfect foliage.

A fit companion plant for this Spleenwort is *A. cicutarium*, a charming species from tropical America, which produces graceful, feathery-looking, light green fronds from a foot to fifteen inches in length. The pinnæ of this species are more or less deflexed, which gives the fronds the appearance of being wrong side up. *A. cicutarium* grows best in a rather warm house, and should at all times be well shaded. The soil best adapted for both these varieties is a rough, open mixture of

peat and sand, with some broken charcoal or sandstone mixed through it.

A. formosum is also an interesting species, and does not seem to be very common, though in cultivation for a number of years. Its fronds are dark green in color, with shining black stipes, and are pinnate, the pinnæ being deeply cut or serrated. The fronds of this species are said to attain a length of eighteen inches at times, but are more often seen from eight to twelve inches long. *A. formosum* should be treated the same as the preceding in regard to soil, shading, etc., and, being a rather delicate rooted species, should be carefully watered.

A. Belangerii is a robust growing species from Java, and produces gracefully arched bipinnate fronds of deep green color. The fronds of this species are also proliferous, and it is easily propagated by this means, as well as by spores. *A. Belangerii* is one of the best of the genus, and will stand much hardship without great injury, small plants being very useful for jardinières or window ferneries.

Another fine, strong-growing species is *A. Fabianum*, also known as *A. fœniculaceum*, the fronds of which are finely divided and reach a length of two to three feet. The mature fronds of this species are dark green in color, and are frequently weighted down by the mass of young plants produced thereon. This Fern will succeed under very ordinary treatment, the chief conditions of which should be a light, well-drained soil and an abundance of water.

A useful member of this genus for rockery or basket work is *A. longissimum*, a species that grows somewhat like a Nephrolepis, though with darker and coarser fronds. The fronds are pinnate, from one to three feet long, and proliferous at the apex. *A. longissimum* is a plant of strong constitution and free growth, and the fronds will be found admirable for many purposes when cut, for when mature they last a long time in water.

A. Serra is a somewhat uncommon sort introduced from Brazil, and produces from a creeping rhizome its bold looking dark green foliage, which attains from one to two feet in height, and is pinnate in form, the pinnæ being large and glossy. *A. Serra* also prefers a warm house, and under favorable conditions is a rapid grower, and makes an effective specimen for exhibition purposes.

Another good sort and of medium growth is *A. viviparum*, which bears some resemblance to *A. Belangerii*, though smaller. Its fronds are from six inches to a foot in length, dark green, and usually nearly covered with young plants; this species being notably prolific in this way. *A. viviparum* is easy to manage, and may be grown in a temperature of fifty-five degrees in good condition. This species is also valuable for small ferneries for table decoration; but it should always be borne in mind that Ferns for the latter purpose should be grown as cool as possible and with good ventilation, so that the fronds may be hard enough to stand a dry atmosphere.

Holmesburg, Pa.

W. H. Taplin.

The Belladonna Lily.

THIS is a bulbous plant and the sole remaining species of the once extensive genus of *Amaryl-lidaceæ*, the botanists having placed the other members under separate genera. The stout bulb supports numerous strap-shaped leaves, which appear in spring and early summer, and after completing their growth die down, to be succeeded, during August, September and October, by the flowers. These are of the spreading funnel-form characteristic of the order, and borne in many-flowered umbels on scapes from twelve to thirty inches high. There is considerable variation in the color of the flowers, which ranges from almost pure white to deep rose. In most forms the flowers are agreeably odorous, but there is a distinct variety, *A. Belladonna blanda*, the light rose colored flowers of which lack fragrance. The species was introduced from the Cape of Good Hope in 1712. There is some conflict of opinion, or perhaps mistake, among the authorities regarding the natural abode of this plant. Loudon and Nicholson place it in the West Indies, Johnson and Moore name the Cape. The latter says of this matter: "The *A. Belladonna* has been said to be employed for poisoning in the West Indies, but this statement appears to be a mistake, and probably refers to some other plant of the same order, the *Belladonna* being a Cape plant."

The Belladonna Lily is not difficult to manage, and may be successfully cultivated in two ways. In one of these a cold frame of southern aspect is chosen, with a soil deep, rich and sandy. The bulbs are planted from six to nine inches deep,

Chrysanthemum, Ada Spaulding—See page 582.

according to size, and sufficiently close for the flowers to form a compact mass when fully developed. They are more imposing in this way and the plants can more readily receive attention. The object of the cold frame is (1) to keep the plants dry after the maturity of foliaceous growth, a state which is found most favorable to the free production of flowers; and (2) to keep the bulbs dry and beyond the influence of frost during winter and spring. The early part of the latter season is the most dangerous period, for if the bulbs are not thoroughly covered with protecting material they are killed, or burst in growth, which is injured by frost so that the plants are of no use that season. All covering should be removed when danger of frost is past, and on the first indication of growth a vigorous development should be encouraged, for unless the plants make sound, healthy growth, and plenty of it, they will not flower well. A free supply of water and liquid manure during the growing period will secure luxuriant foliage.

A few plants in pots are handy in many places, and this is perhaps the most reliable and convenient method of growing them. They are easily cared for after the brief growing season; and set among Ferns, foliage and other flowering plants, to hide the bare pots and naked scapes, the appearance of the flowers in arrangements of low tone is extremely beautiful, while their soft shades have a magical effect among warmer tints. It is this power to bring out new beauties in other subjects, while improving its own, that has won for the plant the popularity it enjoys. The bulbs do not always flower simultaneously, and, therefore, in pot culture it is most satisfactory to plant the bulbs singly. This course has the further advantage of affording greater facility in moving the plants about, and the pots, being smaller than would be required for several bulbs, are more readily obscured when it is desirable to keep them out of sight. Pots seven inches in diameter are large enough for average bulbs. It is a strong point to have the drainage perfect, for although the plants like abundance of water at a certain stage, they are injured by anything approaching saturation. A rich sandy soil is requisite, and this is obtained in a mixture of loam, thoroughly decomposed manure and sand in equal parts. It is best to pot the bulbs early in spring, before the new leaves push forth, and it is well to place them at least two inches beneath the surface of the soil. After being potted they should be placed near the glass in a sunny frame or greenhouse, where protection from frost is assured. When they commence to grow water may be given, and as the plants develop the water supply should be increased and air should be admitted freely during warm weather, and growth encouraged by occasional applications of liquid manure. The supply of liquids must be gradually decreased as the leaves attain their full dimensions, and discontinued altogether when they turn yellow.

The stock may be increased by seeds and offsets. The offsets are removed from the parent bulbs in spring, and they should receive the same treatment as that recommended for the bulbs. With proper care these offsets may be had in bloom two years later. The large fleshy seeds should be sown in sandy soil when ripe, and only partially covered. They germinate readily in a warm greenhouse if kept moderately dry, and when fit to handle should be potted off and treated as older plants. Seedlings usually flower in their third year.

The one vexing quality of the Belladonna Lily is its habit of producing flowers only after the leaves have died away. Its other attractions atone for this defect to some extent, but cultivators have long been anxious to remedy it by crossing *A. Belladonna* with *Vallota purpurea* and other closely allied plants in which foliage and bloom appear together. Whatever these experiments may have proved for the botanist, they have not as yet improved the Belladonna Lily as a garden-plant.

Cambridge, Mass.

M. Barker.

How to Procure Wild Flowers.

IN cultivating our native wild flowers I believe that many amateurs make a mistake in not procuring for themselves from the woods and fields as many of them as come within their reach, or as they could get by a little exertion. To search them out, at least the rarer ones, and know them first in their natural homes; to lift them with one's own hand and note the soil, conditions, etc., in which they grow, and then to copy them as well as may be in some corner of one's garden or grounds, will give more real gratification than the purchase of established plants from a nursery. There are always peculiarities in the location and surroundings of wild plants that are not mentioned in catalogues and botanical descriptions, and to see just where they grow naturally and study their com-

pany, will give one the clearest idea of the place which will suit them best in cultivation.

Take, for example, the wild Violets, of which almost any New England town contains six to a dozen varieties. The time to distinguish the various kinds one from another best is when they are in flower, and they may be successfully transplanted at this season. Go out into the woods and fields in the middle or last of May and look for them. The work may be novel, but one who sets about it in earnest will soon learn just where to look for them. Lift the finest plants, with plenty of their home soil about their roots, using care that they do not wilt. Keep them moist and shielded from the sun, and when planted out in the garden they may need shading and watering for the first few days until their roots get a firm hold of the soil. Such plants well cared for, set at this season, make strong flowering stock by the next spring. If they are inclined to wilt when first lifted, a third or half of the leaves should be removed, which will considerably retard evaporation, so that the roots can keep up a full water supply. At this early season, when Violets are in bloom, many other fine things will be found, such as Anemones, Trilliums, Spring Beauties, Lady Slippers and Ferns. One who begins to collect will be surprised at the number met with, the pleasure each new find gives, and if properly cared for the small per cent. of losses. There is a pleasure in finding for the first time in bloom, in its natural condition, a strange and interesting plant, which cannot be compared to the enjoyment it gives when first viewed in a garden or greenhouse.

But spring is not the only season to collect these wild plants. Scarcely a day passes from May until December when some of them may not be successfully transplanted. On excursions for plants one is apt to overload with implements. A small and light pickaxe about a foot in length, with a handle fifteen inches long, is the only implement needed for most plants. Of course, there are cases where such a tool would not answer, but they are rare. A tin collecting case with a tight cover will keep plants fresh a long time, but a closely woven handle-basket will in most cases answer just as well, and is much lighter to carry. A wet cloth spread in the bottom and another over the plants will keep them cool and moist a long time.

There will always be many desirable things which can be best procured by purchase, but the grower who buys everything regardless of what is within his immediate reach will lose much pleasant and profitable experience.

Transplanting Onions.

AN experiment in transplanting Onions was made last season by Mr. W. J. Green, Horticulturist of the Ohio Experiment Station, the results of which are set forth in the paper which follows, and which was read by him before the Columbus Horticultural Society:

The practice of transplanting Onions when young is not common with gardeners, but it has many advantages which seem to have been overlooked. Seed under forty different names, including about thirty varieties, was sown in the Experiment Station greenhouse February 25th, 1890. The seed came up promptly, and the young plants advanced rapidly in growth, being six to eight inches in height by the middle of April. As soon as practicable two beds or plats of ground were prepared side by side, in one of which the young Onion-plants grown in the greenhouse were planted.

In the other bed seed of the same varieties was sown in the ordinary manner. In all respects, except that of transplanting, the plants in the two beds were treated exactly alike. Both were manured and cultivated alike, and twice during the season, when the weather was dry, both were irrigated. At the proper time the plants in the bed where the seed was sown were thinned, so as to stand the same distance as those that had been transplanted, which was three inches apart in the row, the rows being one foot apart.

The difference in the two beds was very marked from the start. Those that were transplanted commenced to grow at once, none, so far as observed, dying in the operation. Not only were the transplanted Onions much larger at all times during the season, but they had a healthier appearance, besides being more uniform in size. A conservative estimate at any time during the season would have placed the yield of the transplanted bed at more than double that of the other bed.

The difference in cost of cultivation was considerable, the ratio being about one to two in favor of the bed of transplanted Onions. At the first weeding both beds were weedy, but while the weeds were as large as the Onions in the bed where the

seed was sown, making weeding difficult and slow, the task was comparatively easy in the other bed. At the second weeding it was necessary to remove many of the small Onions in the bed where the seed was sown, an operation which is equivalent to an extra weeding. Counting the extra trouble of growing in the greenhouse and transplanting, the work on the two beds was about the same for the whole season—that is, transplanting adds nothing to the cost of growing the crop, aside from the necessity of a greenhouse, hot bed or cold frame, in any of which the plants can be started.

The difference in the time of ripening was about one month in favor of the transplanted Onions, making it possible to use them for bunching, and also to market the crop at an earlier date than could be done with those sown in the open ground. The yield of the transplanted Onions was about double that of the others in most cases, as the following table of some of the leading varieties will show :

Name of variety.	Transplanted.	Not transplanted.
Giant Rocca.....	1,106 bu.	596 bu.
Mammoth Pompeii.....	1,428 "	996 "
Spanish King.....	1,319 "	751 "
White Victoria.....	1,179 "	502 "
Yellow Danvers.....	594 "	398 "
Red Weathersfield.....	779 "	560 "

In the above table the yield per acre is estimated from small plats, and the actual yield on an acre might fall below those given, and yet it is believed that even better results could be obtained by attending carefully to all details in management. It will be seen that the best results and greatest difference in yield were obtained with the foreign varieties. There was a gain with both Yellow Danvers and Red Weathersfield, but less marked than with the other varieties. The greater size and uniformity of the transplanted Onions made the product more marketable in all cases.

The advantages of transplanting Onions may be enumerated as follows: (1) The greater probability of securing a good stand of plants. (2) The saving of labor at the most critical period. (3) Advance in time and maturity. (4) Increase in the crop. (5) Improvement in the appearance of crop, enhancing the market value. (6) The ground is occupied for a shorter period, and therefore it can be occupied by another crop the same season.

This plan may not be feasible for those who grow Onions on a large scale, but it can be followed to advantage by gardeners who do a general market-garden business, and who have the necessary hot-beds or greenhouses. It should be remembered that the foreign varieties with which the above results were obtained are not so good keepers as the varieties commonly grown, but they bring a higher price in the market early in the season.

Ripened Wood Makes Hardy Trees.

I LATELY saw in Woodlands Cemetery, West Philadelphia, a flourishing specimen of *Magnolia fatida* (*grandiflora*) which was nearly twenty-five feet high. I have been satisfied for a long time that it is entirely feasible to have this tree a common one about here if care were taken to plant it in the right place, for there are now several good specimens not far away. But the luxuriance of this one was so evident that it ought to scatter every doubt as to its hardiness. What the tree wants, and what many other so-called "half hardy" things need, is a high, well drained situation, where there will be no unripened shoots when winter comes. Early matured wood is what is wanted, and this the high situation gives. I have seen Deodar Cedars about here flourish well on rocky bluffs with good top-soil. This Magnolia at the Woodlands stands on elevated land not far from the Schuylkill. On its western side is a dwelling house, some thirty feet away; and on every side, though not close enough to prevent its growth, are large deciduous trees, for which this place is famous. Then the numerous monuments about the place also break the wind. Everything tends to make shelter, and if this was given the Magnolia could be made at home in a proper position anywhere in this latitude, so that there is no good reason why the cultivation of this most beautiful and stately of broad-leaved evergreens should not be greatly extended. But the seeds or plants should be had from northern trees, or from those not far south, to have the best chance of success.

In this cemetery, too, as well as in Laurel Hill, are flourishing specimens of the English Holly, a plant rarely seen here out-of-doors. In every case the situation is high, dry and sheltered from the wind and sun. In Laurel Hill I have seen thriving specimens of the common greenhouse shrub, *Azalea*

Indica alba, some of which have been flourishing out-of-doors for many years, yet it is not generally known that this plant is hardy.

Joseph Mechan.

Early Chrysanthemums.—Mr. Gerard, in his excellent note in GARDEN AND FOREST for November 19th, doubts whether it is desirable to spend time in the cultivation of the earliest flowering Chrysanthemums, because they are not equal to the best of the late flowering varieties, and illustrates his position by comparing August Celery with November Celery. It may be granted that Celery after hard frost is more crisp and delicate than that which is earliest in the market, and yet many people who are of the same mind cultivate early Celery, and early Celery always sells well in the market. Just so, the early flowered Chrysanthemums may not be the best of Chrysanthemums, but they are beautiful flowers none the less; they are admired by people of taste, and they will always be grown; and even if we can never have the best Chrysanthemums in early September we may have better ones than we now have, and the people who are working to improve these early varieties deserve encouragement and not criticism. A plant of any of the Desgranges, when in healthy condition, as early as the 10th of August makes one of the most effective of all garden plants. Unfortunately, however, not one plant in twenty-five of this variety will maintain a healthy growth from start to finish, because the thin leaves are not able to endure the heat and drought of our summers. But I feel assured that there is a section of these plants, of which M. E. Nichols is the type, which will give us a very satisfactory list of early Chrysanthemums for flowering from the first of September to the middle of October. Chrysanthemums of this type have all the qualities of good garden plants; dwarf growth, shrubby habit, thick, leathery leaves, and flowers of medium size, freely produced on stiff foot-stalks. From my experience I have no doubt that we shall very shortly have a fair showing of Chrysanthemums with these desirable characteristics.

Pearl River, N. Y.

John Thorpe.

Autumn Flowers.—After Sweet Williams were removed from the margins of our herbaceous borders in July we planted a mixture of Calendulas and Viola "Perfection," the former forming a kind of background. The effect has been quite pleasing, and long after the frost cut everything else down these two plants have kept blooming. Everybody knows how persistent the Calendulas bloom during autumn. This Viola, however, has more than kept it company. It may be raised just as easily as the Pansy, and, if anything, is the hardier of the two. I sow a little seed in a cool frame in spring and get plants into blooming condition in June. I then transplant them in the borders wherever needed, where they bloom for the remainder of the summer until late fall.

Correspondence.

Care in Selecting the Seeds of Trees.

To the Editor of GARDEN AND FOREST:

Sir.—I have been much interested in reading the editorial on the "Improvement of Trees," which appeared in your issue of October 29th. The theory you illustrate by the case of the eastern and western Douglas Spruces, if lived up to and generally adopted, would save many disappointments. About the time the seed of the Colorado Douglas Spruce was planted in Massachusetts I received seeds of this tree collected in Colorado by the late Dr. C. C. Parry. At the same time Burnet Landreth & Sons sent me several pounds of the seed of this tree, gathered on the Pacific side of the continent, to grow for them, as they intended to use the Douglas Fir in their forest-planting in Virginia. The seedlings of both were carefully covered in the autumn of the first year with coarse prairie hay. The seedlings from the Pacific-coast seed were at this time much larger than the others. Both lots grew well the second year; they were planted in the same soil, the Pacific-coast seedlings being in the autumn of the second year still much larger than the others. Each lot of seedlings had the same covering the second winter. When they were uncovered the following spring the Colorado seedlings were as fresh as Norway Spruce or Scottish Pine seedlings of the same age, having wintered perfectly. The Pacific-coast seedlings turned brown wherever they penetrated through the covering of hay, although they were green where they had been well covered. When the time came for them, however, to commence their new growth they all died.

The Douglas Spruce is by no means an exception. I have met with several other cases as marked as the one I have related. Many years ago there was a great demand for Red Cedars for ornamental planting in the west. Many people liked them for hedges. We collected our seeds from native trees growing on the bluffs here. These trees did not, however, produce enough seed to supply the demand, and we ordered five bushels of it from western Tennessee and the same quantity from southern Illinois. We had the same experience as with the Douglas Spruce. The seeds collected here produced hardy trees; the others produced tender trees. At another time Black Walnuts did not fruit well in our county. We gathered what we could find and ordered a large quantity of nuts from southern Illinois. The plants raised from these southern plants made a much larger growth than ours during the first season. The following spring ours were all alive with terminal buds, while the southern plants were killed to the ground and went to the brush-pile. I could cite many other instances as marked, but these ought to be enough to convince any reasonable man that it is necessary to select seeds of trees with reference to the locality where the seedlings are to grow.

Recent Publications.

The Silva of North America. A Description of the Forest-Trees which grow naturally in North America exclusive of Mexico. By Charles Sprague Sargent, Director of the Arnold Arboretum of Harvard University. Illustrated with Figures and Analyses drawn from Nature by Charles Edward Faxon, and engraved by Philibert and Eugène Picart. Volume I. *Magnoliaceæ—Illicineæ*. Large 4to, pp. ix. + 119; 50 plates. Boston and New York: Houghton, Mifflin & Co. 1891.

It is with a sense of profound gratitude and with the highest admiration for the immense labor devoted to the work that we welcome the appearance of the first volume of this magnificent book. Professor Sargent has been engaged in the accumulation of the material now collated and given to the world for a large number of years, and the result will rank with the works on science and art that are recognized as classics the world over.

The book is sumptuously printed on heavy paper and cut with broad margins. The illustrations are superb, the descriptions are excellent, and the notes on geographical distribution, history and economic importance are of the highest interest and value.

The descriptions of genera and species, which follow the sequence adopted in the "Genera Plantarum" of Bentham and Hooker, are prefaced by an account of the various publications which have been especially devoted to our trees, the earliest being Humphrey Marshall's "Arbustum Americanum," and the most recent noted Professor Edward L. Greene's "West American Oaks."

The author's definition of a tree is certainly the most rational one. He says: "The line which divides trees from shrubs is a purely arbitrary one, and an attempt to separate them is often unsatisfactory. A division based on habit, rather than on size, seems, upon the whole, more easily applied than any other, and therefore less objectionable. So, for the purposes of this work I have considered as trees all woody plants which grow up from the ground with a single stem, whatever size or height they may attain." As to the number of species coming within this definition it is stated "The forests of North America, exclusive of Mexico, are now believed to contain four hundred and twenty-two, besides numerous varieties."

The question of nomenclature is treated of in the following sentences: "I have adopted the method which imposes upon a plant the oldest generic name applied to it by Linnæus in the first edition of the 'Genera Plantarum,' published in 1737, or by any subsequent author, and the oldest specific name used by Linnæus in the first edition of the 'Species Plantarum,' published in 1753, or by any subsequent author, without regard to the fact that such a specific name may have been associated at first with a generic name improperly employed. The rigid application of this rule leads to the change of many familiar names and considerable temporary confusion. But unless it is adopted, anything like stability of nomenclature is hopeless, and the sooner the changes which are inevitable in the future are made, the more easily students will become accustomed to them and acquire a knowledge of the correct names of our trees." This position will be heartily welcomed by almost every American botanist. Indeed, we believe that the publication of this great work on this principle will practically remove all opposition to the method here adopted, and

which some of us have for many years foreseen as the only escape from a very troublesome question.

The following species are described and figured in this volume: *Magnolia fatida*, *M. glauca*, *M. acuminata*, *M. tripetala*, *M. Fraseri*; *Liriodendron Tulipifera*; *Asimina triloba*; *Anona glabra*; *Capparis Jamaicensis*; *Canella alba*; *Gordonia Lasianthus*, *G. Altamaha*; *Fremontia Californica*; *Tilia Americana*, *T. pubescens*, *T. heterophylla*; *Guaiacum sanctum*; *Xanthoxylum Clava-Herculis*, *X. cribratum*, *X. Fagara*; *Ptelea trifoliata*; *Helietta parvifolia*; *Amyris maritima*; *Canotia holacantha*; *Simaruba glauca*; *Kæberlinia spinosa*; *Bursera Simaruba*; *Swietenia Mahagoni*; *Ilex opaca*, *I. Cassine*, *I. vomitoria*, *I. decidua* and *I. monticola*.

The "Silva" will be completed in twelve volumes, to be issued two each year. The price is fixed at \$25 per volume. It ought to find a place in every public library in this country and abroad, and the proprietor of every country-place will be one thing short of complete equipment until a copy of it is within reach in his drawing-room.

Columbia College, New York.

N. L. Britton.

Our New England: Her Nature Described by Hamilton Wright Mabie, and Some of her Familiar Scenes Illustrated. Boston: Roberts Brothers.

We do not often have occasion to speak in these columns of a Christmas "gift-book." But this one has merits beyond those that make the usual example of its class a more or less desirable object to lay on the centre-table. It is a long quarto volume, illustrated by reproductions of photographs from typical New England scenes, beautifully printed as a rule, always interesting in their subject matter, and sometimes—as in the view of the Exeter River, the "Milking Time" and the "Country Road in Summer"—really charming. Unfortunately, however, in a seeming desire to enhance the "decorative" effect of these simple transcripts from reality, each has been printed on a page partly covered with pen-and-ink drawings of the sort which, when etching margins are similarly defaced, are called "remarks." In some cases these pen-and-ink accessories are modest enough to injure the effect of the main picture but little. In other cases, however, they are most unfortunately obtrusive, and they have small merit of their own to excuse their intrusiveness.

But better even than the photogravures is the delightful essay of Mr. Mabie, which, while following lines that have often been trodden—with its four chapters devoted to the aspects and moods of the four seasons—gives us a genuinely fresh impression of New England nature. One passage, as true as it is fresh, runs thus: "First impressions linger long after fuller knowledge has shown them to be mere illusions: and the first impressions of New England were distinctly unfavorable. If the colonists of 1620 had landed in Plymouth Bay in June instead of December the report that went abroad of New England would have conveyed a genial and mellow instead of a harsh and bleak import. The melancholy monotone of the waves breaking on a 'stern and rock-bound coast' would not have lingered in the ear as the dominant note of the New England landscape; nor would short and bitter days and snow-beleagured forests have furnished the atmosphere and background of New England scenery as often conceived by persons at a distance. That December landing was not without obvious advantages in the way of discipline, but it gave occasion for a misapprehension which still exists in many minds. The year in New England has four well defined seasons, and winter is one, not all, of them." This, we repeat, is at bottom quite true. But perhaps Mr. Mabie has not laid the greatest blame exactly where it belongs. It is not facts which impress later generations so much as the report of these facts, and the report which makes the profoundest impression and echoes longest is the report voiced by some form of art. It has been, we think, the poem from which Mr. Mabie quotes which is chiefly responsible for the popular idea, current at home and abroad, with regard to New England as a typically inclement region. Of course, if the Pilgrims had not chanced to land in December, Mrs. Hemans would not have written her thrice-popular verses in the strain she chose. But the fact that she wrote them, not the fact that she had historical excuse for writing them, seems to us the real lion that has stood in the path of a general understanding that New England has delightfully hot summers as well as painfully cold winters. It matters not who writes the history of things—it is the person who sings songs about them, in a way to catch the popular ear, who really moulds popular impressions. And is not Mr. Whittier in this sense another sinner? Why, we ask—we who think the New England summer and autumn the most delightful earth can offer—why did he write "Snow-bound" instead of a

poem called, for instance, "Under Green Apple-boughs" or "By a Blue Summer Sea"?

And this suggests the only fault we have to find with Mr. Mabie himself as an exponent of New England charms. He does not pay enough attention to the charms of her sea-coast. It is delightful and beautiful enough in itself to deserve high honor at the hands of any commentator, and its importance is increased by the fact that these shores only on the whole long reach of our Atlantic seaboard have real picturesqueness and varied beauty. There is subject matter for a dozen essays in the variety which they reveal, from the noble boldness of the coast of Maine to the humble, green, mellow softness of Buzzard's Bay and the adjacent parts, where the breath of the Gulf Stream transports us far enough away from all conventional ideas of "stern and rock-bound coasts" and to the pastoral charm of the broad reaches which face Long Island Sound. May Mr. Mabie be moved by the spirit of these coasts to write another essay wherein their moods and aspects shall be chronicled!

Exhibitions.

Autumn Flower Show of the United States Nurseries.

THE exhibition of flowers and plants which filled the immense ground-area of Madison Square Garden last week displayed in a remarkable manner the resources of a single establishment. The transportation of the collection in covered vans from Short Hills, New Jersey, where the United States Nurseries are situated, is said to have cost Messrs. Pitcher & Manda \$2,000. The principal attractions were, of course, Chrysanthemums and Orchids, but there were great numbers of other green-house plants—Specimen Palms, Cycads and Ferns, arranged in a most effective way, so that the Garden from the upper galleries presented a striking picture. The season was so well advanced that the great mass of Chrysanthemums had passed their prime, but the late varieties were fairly well represented. Fresh blooms every day took the place of those that had faded, and many novelties were introduced as the show went on. An immense flower of a new seedling named *The Tribune* was not shown until Saturday, and several others made their first appearance on the last day of the show. *The Tribune* was grown in a five-inch pot, and the flower, which is closely incurved and whorled, is very deep and substantial. The cut bloom exhibited was about seven inches across and of a rather creamy white, with a few of the very outer florets pink-tinted. Most of the novelties in Chrysanthemums which originated this year at the United States Nurseries have been described in previous numbers of this journal.

The strength of the display as a Chrysanthemum show was in the massing of great numbers of plants, the different colors being skillfully mingled in soft harmonies. A solid square of rich red Cullingfordii and masses of the pure yellow of W. H. Lincoln and Grandiflorum were the most conspicuous.

In the very centre of the arena was a bank of *Cypripediums* by the hundred, with well grown specimens of *Adiantum Farleyense* scattered among them, while behind them rose tall Palms, and above them hung great numbers of epiphytal Orchids. The richness of this collection of *Cypripediums* will be understood when it is known that on a stage not far away there were 135 distinct varieties in bloom.

At the eastern extremity of the display was a striking group of fruit-plants, Bananas, Pineapples and other Bromeliads, with Agaves and Cacti rising from a carpet of succulents. Scattered among the collection and almost lost in the great variety were many rare and interesting specimen plants. Among these we may note *Phoenix Roebelinii*, figured in GARDEN AND FOREST for June 4th, 1890, and a wonderful specimen of *Zamia pungens*, which was much admired. Among the best Orchids were fine examples of the white *Lycaste Skinneri*, *Lalia Autumnalis alba*, *L. Eyermannii*, *L. Gouldiana*, *L. Arnoldiana*, *Phajus Blumei*, *Cypripedium Ashburtonia expansum*, *C. Harrisianum superbum*, *C. magniflorum*, *C. Masereelianum*, *C. Schroderae*, *C. Leucorhodum*, *C. Tonsum superbum*, *C. cardinale* and Charles Canham. Besides these there were many such oddities as the Cocaine-plant, the Cinnamon-tree, the Telegraph-plant and the Cayenne Pepper-plant.

The exhibition was largely attended during the entire week, and the question was often asked: "If a single firm can make such a creditable display, why cannot the Horticultural Society of New York have exhibitions which would be worthy of this great city?" Flower lovers go from here to Philadelphia and Boston to enjoy the displays there every spring and autumn.

There is no lack of commercial growers in this neighborhood, and there are admirable private collections, and yet but for the enterprise of such firms as Pitcher & Manda and Siebrecht & Wadley no flower show could be seen here from one year's end to another.

Notes.

At the annual meeting of the Pennsylvania State Forestry Association, held in Philadelphia last Friday evening, Rev. Dr. J. P. Lundy was chosen President. Addresses were delivered by Mr. B. E. Fernow, Chief of the Forestry Division of the Department of Agriculture, Mr. Herbert Welsh and Mr. Burnet Landreth.

Azalea Indica (Robert le Diable) is described by the *Illustrirte Gartenzeitung*, of Vienna, as a new variety, first exhibited by Monsieur V. Cuvillier last April. It has "enormously large single flowers, strikingly characterized by their rare orange-cinnamon color, which is enhanced by a large black spot, with metallic reflections, that covers more than half the flower."

If the accounts in Russian papers are true, horticultural shows in St. Petersburg are not conducted on very scientific principles. At an exhibition of orchard-fruit and flowers which was held last October it is said that 500 prizes were distributed, one at least falling to almost every exhibitor; and one man was rewarded for some fine apples which he confessed to having bought on the market place, never having owned or cultivated a garden in his life.

Part of the money appropriated not long since for the establishment of small parks in Brooklyn will be at once expended for a pleasure-ground in the Eighteenth Ward. It will be bounded by Knickerbocker and Irving Avenues and by Starr and Suydam Streets, and will contain 104 city lots, measuring 25x100 feet, which will be paid for at the rate of \$1,000 a lot. It is proposed to call the spot "Stranahan Park" as a merited compliment to the citizen who was chiefly instrumental in the establishment of Prospect Park some thirty years ago.

The International Exhibition, which is to be held in the island of Jamaica, will open on January 27th, 1891. A horticultural display will be among its chief features, and will doubtless prove of great interest to northern botanists and horticulturists. Persons desiring to exhibit in any department should communicate with Mr. T. T. Stokes, of 44 Boylston Street, Boston. Through the good offices of Mr. L. D. Baker, of Jamaica, who is President of the Boston Fruit Company, it has been arranged to transport free of charge all exhibits from the New England States.

The "Report on the Progress and Condition of the Botanic Garden in Adelaide during 1889," recently published by Dr. R. Schomburgk, the Director of the garden, says that South Australia never had such favorable, abundant rains as during the year in question. The Roses suffered, indeed, from excessive moisture and then from excessive heat in the months of November and December, but the carpet-beds flourished wonderfully. Among the plants which had promised well were the new Japanese food-tuber, *Stachys affinis*; the new Mexican Vine, *Vitis Mexicana Mocin*; *Agave Sisalina*, the plant which furnishes Sisal-fibre, and *Lathyrus silvestris*.

According to a correspondent of *The Tribune* the groves of English Walnut, just coming into good bearing in Anaheim, Los Angeles County, produce from \$400 to \$500 per acre. Only twenty-seven trees are planted to an acre, but each tree will yield \$20 worth of nuts. Nineteen years ago Fresno County was a desert. Wheat could not be raised even on the valley land, because of the excessive drought in summer. In 1871 the first irrigating canal brought in 500 settlers. These have now increased to 25,000 colonists, while land formerly held at \$2.50 per acre now commands from \$50 to \$500 an acre. The county now has sixteen canal systems, 300,000 acres in grain, 20,000 in vineyards and 3,000 in orchards.

An account of Rangemore Hall, near Burton-on-Trent, the estate created by the famous brewer Bass and now occupied by his son, Lord Burton, was recently published in the *Gardeners' Chronicle*, and gives an idea of the extent of glass which may form a feature of a great English establishment. The houses are all heated from one boiler-house, which is sixty feet below the level of the gardens. Grapes are grown in six houses, Peaches in seven, Figs in two, Cucumbers in two, Strawberries in one, Tomatoes in one, and Melons in two; those for flowers include one for Azaleas, one for Camellias,

one for East India Orchids, one for Cattleyas, one for cool Orchids, one for Eucharis, two for Carnations, two for Gloxinias, and two for Cyclamens; to these must be added a stove, a fernery, a propagating-house, a conservatory, and eight pits for various flowers. Twenty-six gardeners care for these houses and the grounds, and the unmarried men among them live in a comfortable house in the gardens, which is provided with a well stocked reading-room and a horticultural library of 300 volumes.

It is said in a late number of the *Daytona* (Florida) *Messenger* that in many parts of Florida old Indigo-fields are still to be seen, together with vats, drying-houses, store-houses, etc., but for some reason, perhaps because the preparation of Indigo into a marketable article was expensive and unwholesome, the cultivation of this plant has been suspended. The annual export of indigo from the southern states once amounted to about 1,000,000 pounds, but now there are only a few places in Georgia and South Carolina where it is cultivated at all. The Department of Agriculture is making efforts to introduce the cultivation of this plant again into Florida and Louisiana, where, under improved methods of preparation for market which materially lessen the cost of the operation, it ought to prove profitable. The plant requires a moderately rich soil and is ready to cut about three months after the seed is sown. The coloring matter does not exist as indigo in the plant, but when it is steeped in water and subjected to certain processes the blue color is brought out.

Mr. L. Paparelli, who came last year from Italy to assist Professor Hilgard in the Experiment Station at Berkeley, has prepared a statement for Olive-growers in California concerning the methods of pickling the fruit employed in Italy. The olives must be picked by hand some six weeks before they reach maturity. The usual process is to steep them in a solution of caustic soda at the rate of about five ounces to a gallon of water. After soaking a few hours soft water is poured upon them several times until it flows away clear, when the fruit is placed in kegs of brine consisting of one ounce of salt and thirteen ounces of water for each pound of olives. When they are preserved without lye the olives are placed in a wooden vat and submerged in pure water covered with Lemon leaves. The liquid is changed every hour for a month, after which the fruit is placed in vats, with first a layer of salt, then one of olives, then salt again, the proportion being twelve pounds of salt to a hundred pounds of olives. After remaining in the salt for two days clean water is added, and another layer of an inch of salt is placed on top, and in a month after this treatment they are fit for use. The olives are improved by placing aromatic herbs like Fennel among them after the first treatment.

Fuller, the author of the famous "Worthies of England," published about the middle of the seventeenth century, says with regard to the gardens of Surrey: "Gardening was first brought into England for profit about seventy years ago, before which we fetched most of our cherries from Holland, apples from France, and had hardly a mess of rath peas but from Holland, which were dainties for ladies, they came so far and cost so dear. Since gardening has crept out of Holland to Sandwich, Kent, and thence to Surrey, where, though they have given £6 an acre and upward, they have made their rent, lived comfortably, and set many people to work. Oh, the incredible profit by digging of ground! for though it be confessed that the plow beats the spade out of distance for speed (almost as much as the press beats the pen), yet what the spade wants in the quantity of ground it manureth, it recompenseth with the plenty of food it yieldeth, that which is set multiplying abundant-fold more than that which is sown. 'Tis incredible how many poor people in London live thereon, so that, in some fashion, the gardens feed more people than the field." The reference in the last sentence is evidently to the market-gardens which already abounded in districts that are now a solid part of London, but were then purely suburban in character—Battersea, for example, and Bethnal Green.

Professor Cook, of Michigan College Experiment Station, has been continuing experiments with the Plum Curculio, and comes to the conclusion that while spraying with the arsenites may be at times successful, it is not always so. Some small trees heavily loaded with fruit were sprayed last season, and though no rain washed the poison away, in less than a week all the plums were stung. Professor Cook therefore concludes that the old reliable method first suggested by the father of Mr. J. J. Thomas, the well known pomologist, remains the surest, cheapest and best method of banishing the Curculio from Plum orchards. With this process the Curculio may be allowed to work until it has sufficiently thinned out the fruit,

thus rendering the grower a conspicuous service, after which the jarring can begin and the remaining fruit can be saved clean, large and sound. If the fallen fruit is gathered every day under this process the work will be less and less every year. The mallet with which the trees are struck should be well padded, and, even then, unless great care is used serious damage may be done to the trees. In some cases a spike is driven into the tree, and then an iron or wooden mallet without a pad may be used, or a limb may be sawed off to receive the blow. Professor Cook thinks it would pay fruit-growers to set Plum-trees thickly among other fruit-trees. The Curculio prefers the plum, and will therefore leave apples, cherries and peaches untouched, and the enemy can be fought on the Plum-trees alone. In this way not only a profitable crop of plums can be secured, but the other crops are protected with no other extra expense.

The death in Paris of Dr. J. Triana, the distinguished botanist of New Granada, at the age of sixty-two years, is announced in the last issue of the *Revue Horticole* which has reached us. For ten years he explored the flora of his native country as a member of the Scientific Commission directed by Codazzi, and then established himself in France, where the position of Consul-General of New Granada enabled him to reside, for the purpose of describing his collections. His work, however, was always hindered and finally had to be abandoned for the want of financial support from his Government, and his "Prodromus Floræ Novæ-Granadensis" did not proceed beyond the *Sapindaceæ*. Triana was associated with the late Dr. Planchon in the publication of many of his new species. He published, too, important memoirs on the *Guttiferae* and upon the *Melastomaceæ*. Monsieur Triana, in spite of the numerous discouragements he had to encounter in the last years of his life, never ceased to interest himself in the plants of his native country, and in their applications in medicine, in the industrial arts, in horticulture and agriculture. He was a foreign member of the National Agricultural Society of France, and left many devoted friends in France.

In the death of Mr. Shirley Hibberd, which occurred somewhat suddenly on the 16th instant at Kew, horticulture has lost one of its most devoted apostles, and his country an earnest worker who was always in the van of every movement, horticultural or agricultural, intended to promote the interests of either, and of the community at large. For nearly forty years Mr. Hibberd stood in the front rank among English horticulturists, having from the time when he was quite a young man, up to within a few hours of his death, devoted himself with an ardor equaled only by his ability to the affairs of the garden. Experimental gardening was his passion, and it is not too much to say that the present high position of English horticultural art is largely due to Mr. Hibberd's careful experiments, keen observation and thorough teaching. Vegetables of various kinds, fruit, Roses, Pelargoniums, Chrysanthemums, Ivies, besides many other plants, were collected and cultivated by him solely with a view to improvement in the plants themselves, by crossing and selection, or in the methods of cultivation. Mr. William Watson sends us an appreciative estimate of Mr. Hibberd's capacity and attainments, from which we extract the following: "He was a most successful teacher. As a writer and lecturer on horticultural subjects he had no equal. He spoke from experience; his knowledge of his subject was thorough; he rarely theorized. While possessing a deep and wide knowledge, he also possessed to a remarkable degree the art of conveying it to others both by writing and orally. I never heard a speaker who was better able to inspire one with enthusiasm, to work one up to the highest pitch, to carry one along with him, than Mr. Hibberd. It is probable that his success as a speaker and writer was largely due to the zeal with which he pursued various other subjects besides those which he preferred to be publicly identified with. His knowledge of poetry, for instance, was exceptional. A lecture on Shakespeare which he delivered in Kew scarcely a year ago astonished by its cleverness even those who knew that Shirley Hibberd was no ordinary man. He probably knew every line of Tennyson's best poems. I have heard him, when discoursing on Tennyson, recite portions of the 'Idylls of the King' and 'In Memoriam' in such a way as showed pretty clearly that he had them all by heart. His originality, earnestness and clear-headedness, his restless energy, manliness and downright good nature were shown in everything he did. Among the many eminent horticulturists whom death has claimed this year, the one whose place cannot easily be filled is Mr. Shirley Hibberd. He was born in 1825, was married twice, and leaves only a little daughter of six years behind him."

Protection of the Yellowstone Park.

IT is to be hoped that Congress will take some definite action this winter on the bill now before the House of Representatives for the enlargement, protection and maintenance of the Yellowstone Park. The preservation of the national park is a matter in which a large number of people throughout the country feel a deep interest and patriotic pride. They believe in its preservation for the purposes for which it was originally set aside, and at the same time realize its importance from an economic point of view. Thousands of citizens have memorialized Congress for the passage of some measure looking to its better protection.

The park is a high plateau with an average elevation of nearly 8,000 feet, surrounded on nearly all sides by mountains rising from 2,000 to 3,000 feet above this broad tableland. Numerous streams from the high mountains pour their waters into the park, from which, by means of three large rivers, the greater part of it leaves this elevated country for the more arid regions below. Hundreds of lakes, many of them of large size, lie scattered over the plateau. Yellowstone Lake, one of the grandest bodies of water in the world at so high an altitude, presents a magnificent natural reservoir twenty miles in length, with a breadth, across its greatest expansion, of fifteen miles. Two large rivers, the Yellowstone and the Snake, find their sources in these lakes and mountain recesses. In all the vast Rocky Mountain country there are few, if any, areas of equal extent so admirably adapted for a national forest-reservation, and none which present greater advantages as a natural reservoir for the storage of water. Over eighty per cent. of the park country is covered with a coniferous forest. For the collection and preservation of this water supply the forest of the park and the adjacent territory is of incalculable value. It is indeed a prime necessity. The importance of this water in an arid region,

and one with a constantly increasing population, cannot be overestimated. It is safe to say that without the forest and with the diminished water supply, which would naturally follow, the grand scenic effects of the park would be wholly wanting. The geysers, hot springs and water-falls would be despoiled of their charm.

At the time the park was originally set aside as a pleasure-ground for the people the boundaries were very loosely defined, the country being almost a *terra incognita*. With our present knowledge of the physical features of the region these errors can easily be rectified. The proposed bill enlarges the park to the south and west, including a large area of forest-covered mountains now wholly unprotected. These mountain lands are useless for agricultural and grazing purposes, but they are invaluable as the sources of the main streams and the feeders of the Yellowstone Lake and Snake River. Besides its economic value, this proposed extension of the reservation would give to the park picturesque valleys and bold panoramic scenery, both of which it now in a great measure lacks.

A bill to meet the present requirements of the park has been before Congress for eight years. It has passed the Senate four times, only to be lost in the House. In the present Congress a carefully considered bill has passed the Senate, and has been reported to the House from committee with one or two amendments. No objection whatever is raised to the proposed enlargement or the provisions made for the punishment of criminal offenses committed within the reservation, the two most important objects of the bill. Yet the bill is again liable to fail of becoming a law owing to a small but persistent lobby, who are determined that it shall not pass without an amendment granting an exclusive privilege to a railway company to lay fifty or sixty miles of track in order to reach Cooke, a small mining camp lying just outside the north-east corner of the park.

Those interested in the park, for many obvious reasons, object to the admission of any railway. They see in such an admission the beginning of the end. They are quite willing to adjust the northern boundary so as to allow not only the railway but traffic of all kinds to reach the mines without going through the reservation. This object can be easily attained by making the Yellowstone River the north-eastern boundary, an excellent physical feature which all could recognize. Curiously enough the Montana Mineral Railway Company, the corporation asking for this franchise, objects to this adjustment of the northern boundary, because, as they say, it would allow any railway to build to Cooke. What they really desire, it seems, is an exclusive privilege which the proposed amendment would give them, and without which they oppose the bill. It is far better that people along the line of the railway should live under state jurisdiction rather than reside within the reservation. The people interested in Cooke, who consider a railway essential for the development of their property, prefer that the track should run wholly outside the park. They are becoming irritated at the delays caused by the small number of individuals who, for their own personal ends, object to any modification of the boundary and insist upon the railway running through the park.

Since the matter was first agitated in Congress large tracts of the country which it is proposed to add to the park have been devastated by forest-fires either maliciously or carelessly started. Large herds of elk, deer, sheep and moose have been wantonly slaughtered for their hides by skin-hunters. By those qualified to give an opinion, it is stated that the country immediately south of the park, which it is proposed to add to it, is one of the favorite breeding places of the elk. Secretaries Lamar, Vilas and Noble have each in their annual reports urged the passage of a similar bill to this one now before Congress. It is certainly not too much to ask of Congress that they take some action in this matter and protect from vandalism of all kinds this most valuable forest and game reservation.

THE New York Society for Parks and Playgrounds was recently incorporated at Albany. Its President is the Hon. Abram S. Hewitt. Among its Trustees are Dr. Felix Adler, Mr. De Witt J. Seligman and Mr. Andrew H. Green, and among its other incorporators are Bishop Potter and Mr. Erastus Wiman. These names we cite from a much longer list to show that neither sectarian nor political influences will control the new organization, but a pure desire on the part of representative citizens of all kinds to promote the welfare of the poor children of New York. One of the Trustees, in an interview reported in the *New York Sun*, says that the first object of the Association will be to obtain a greater number of suitable places in our larger parks where children of all ages will be allowed to play and can be provided with inexpensive amusements like heaps of sand and swings. Then vacant lands will be rented for temporary playgrounds in various localities, and an effort will be made to obtain an exemption from taxation for such lands. Below Fourteenth Street, where unimproved lots can hardly be found, play-houses will be established to take, as far as possible, the place of open grounds. The city authorities will be influenced to provide without delay the small parks in thickly populated districts which were authorized by the act of 1887 while Mr. Hewitt was Mayor; and arrangements will be made for sending bodies of children to the parks in summer under proper control and guidance, so that their diversions may be healthful and safe. To secure competent superintendence for the different play-grounds will, of course, be one of the most difficult tasks of the Society; but the aid already promised by Mr. D. J. H. Ward, the instructor of Dr. Adler's well known school, and by such experienced teachers as Professor Woodhull, promises well for success in this direction. The good which this Society may do is incalculable, and it is to be hoped that it will have generous support. Much more will be secured than the temporary amusement and the physical improvement of poor children. Such influences as will be brought to bear upon them ought to have a far-reaching effect upon the development of their characters and their intelligence, and these proposed playgrounds, and the devoted teachers who will superintend them, may rescue many little ones from lives of degeneracy and crime.

There is little fear that the united judgment of the organizers of this movement will countenance any project which may be objectionable. A few zealous friends of the children seem to forget that there are larger people who have equal need of playgrounds, and they are urging some very destructive changes in the design of Central Park. It will not be necessary to sacrifice the beauty of the park, which means its highest usefulness, to make provision for the children. Park ground is a necessity as well as playground, and the growing city must have more of both.

Private Grounds and Enclosures in Cities and Towns.—I.

THERE is a strong contrast between American and European ideas as to the character and function of private grounds, be the area surrounding a house large or small. In Europe the idea is that of seclusion; in the United States it is rather one of inclusion. In Europe the space surrounding the dwelling is treated as an out-door extension of the dwelling itself; a high wall encloses it, and so sacred is its privacy that the gaze of a stranger into its precincts is held as something to be guarded against almost as rigorously as actual trespass. Not only is this the case with country or suburban grounds, but in England, in cases where city houses chance to have an area of a few yards between their fronts and the street, this space is also habitually shut in with a high and solid wall.

With us, the ground surrounding a dwelling is treated, in effect, as an intermediate territory; a transition between the freedom of the public way and the privacy of the household. This character has been intensified, rather than diminished, of late years, with the growth of wealth and æsthetic culture in our country. In our suburbs the tendency is toward the removal of all barriers, not only between the house-grounds and the street, but also the elimination of all boundary marks

between the grounds of adjacent dwellings, giving the houses of a neighborhood the appearance of standing in a space common to them all.

It would be an interesting task to trace the reason for this radical departure from the domestic traditions of our race in the Old World, but it might require a research in the province of sociology so extensive as to forbid present consideration. Our democracy undoubtedly has something to do with it. While possibly a minor motive may be the indulgence of a love of display, harmless in such a manifestation, this characteristic seems more likely to proceed from an intuitive recognition of the fundamental fact of a democratic commonwealth: That the individual is a portion of the public, to which he owes the duty of sharing, so far as he may, the enjoyment of the things of beauty that he may be privileged to possess.

There are desirable elements in both systems, and it would be an excellent thing could the best features of each be combined. The American custom contributes largely to the adornment of the town or city; the placing of dwellings in such relations to each other and to the public creates an atmosphere of frankness, of hospitality, and of neighborhood friendliness and freedom. It also cultivates the virtue of voluntary respect for private rights and privileges, and it is notable that in communities where this absence of bounds and barriers prevails, the abstention from trespass is, at least, as marked as where walls, hedges and fences forbid passage. Exclusiveness is a habit not native to Americans, and in our out-door life there is little disposition to avoid the public gaze. Upon our private grounds it is customary to play at tennis, croquet and other games with entire indifference to lookers-on from the adjacent highway.

Yet there is a great charm in a "close"; in an open place securely walled or hedged about, where members of the household may enjoy the open air in the same seclusion that exists within the walls of the dwelling. An advantage of such a feature, besides its retired character, consists in the possibility of its use at times and seasons when resort to the more open grounds might be inconvenient or uncomfortable. There is more likelihood of shelter from winds that in an exposed situation would be unpleasant at times; and this shelter would enable its use on pleasant days both earlier in the spring and later in the autumn than would be practicable otherwise. It is true that the broad piazzas peculiar to the better class of rural dwellings in this country largely answer to purposes of this nature, yet in certain respects they do not fully serve as substitutes for the "close."

The treatment of this feature should, of course, be quite different from that of open grounds; its service as an out-door portion of the dwelling should be markedly recognized in a more formal treatment, possibly combining the garden, the bower, and a suggestion of the conservatory, with the free use of tender and tropical plants in ornamental pots. Some sheltered angle beside or behind the house should be chosen, with careful reference to prevailing winds and to the sun, and the enclosing wall could easily be made a pleasing feature of the architecture of the house.

Boston.

Sylvester Baxter.

The Autumn Flora of the Lake Michigan Pine Barrens.—I.

IT is the good fortune of botanists and admirers of our native plants who live at Chicago to have within a short distance of the city a region as yet but little disturbed by the hand of man. A ride of a few miles takes one to a Pine-barren and a succession of sand hills and dunes extending around the head of Lake Michigan to Michigan City and beyond. And one can hardly avoid entertaining the hope, even at the expense of the owners of the property, that it will remain in this condition for some time to come. Though factories and dwelling houses have sprung up in the woods and swamps, one can still roam over spots where towns only exist on maps and in the minds of speculators. And since the value of the land to the cultivator is slight, though yielding fair returns to the market-gardener where the sands are not shifting, the prospect of speedy settlement is not bright. The scanty timber spared by numerous fires and springing up in their track is mainly composed of Pines and Oaks, with Cedars, Poplars, Birches, Tupelo and Sassafras in localities suited to their growth. The western part of the region is low and generally swampy, the long ridges of sand rising but slightly above alternating sloughs running parallel with them and the shore of the neighboring lake. Eastward the wind has piled the sand into hills, the depressions among them being dry or occupied by ponds and swamps. There is much less regularity in

the surface structure than in that of the western part. The hills are mostly held in position by a scattered growth of trees and shrubs and plants characteristic of the sand dunes, except near the shore, where the wind piles the sand into great drifts, which often change their form and position. There is a rich variety in the plants of the whole region, when we take into account the entire season of growth, although the conditions of soil and moisture, and the modifying influence of the lake, are very variable. It is the autumnal flora of the western or more typical Pine-barrens which I purpose to notice in its most striking feature, as seen in the month of September. From the eighty to one hundred plants whose season is autumnal or reaches over into autumn, I have selected the following as most characteristic.

The Golden-rod claims more than a dozen species; two of these are the most abundant, each in the place most suited to its growth. *Solidago nemoralis* grows throughout in the dry grounds, its grayish stem and leaves according well with the color of the ground beneath. *S. Ohioensis* takes the grassy borders of the sloughs or the moist and open spaces, which it clothes with stretches of yellow, often of great extent. It is a smooth plant, about two feet high, with narrow leaves, the radical pretty long; the stem is terminated by a showy corymb from two to six inches in diameter. Close by the lake is a peculiar species, *S. humilis*, or this species running into the variety *Gilmanii*. It is confined to the ridge of sand that skirts the shore, and is very local in this respect. The flower-heads are large, few in number and nearly sessile along the upper part of the stem. Several stems, some of them three feet long at times, usually spring from the same roots and rise obliquely in different directions. One of the handsomest kinds is *S. speciosa* or its variety *angustata*. They bear a long thyrselike panicle of bright flowers, with the smooth stems densely covered by thick leaves, making a very sleek looking plant. These occasionally branch at the top, forming a cluster of thyrsoid panicles. They are found in the driest situations, and when massed, as they sometimes are, the effect is very showy. *S. Riddellii* is a companion of *S. Ohioensis*, but is much less seen in the barrens than in prairie regions. It has a corymb much like that of the latter, but more compact. It is very distinctly marked by its narrow, conduplicate leaves, sheathing the stem at their insertion and gradually curving away from it. Fine specimens of *S. rugosa* are also found here, well distinguished by its peculiar rugose leaves from the allied species, *S. ulmifolia*, seen also in the regions clothed with Oaks and White Pines.

The most showy plants upon the ridges are two species of *Liatris* or Blazing Star, *L. scariosa* and *L. cylindracea*. Then in the same localities as *Solidago Ohioensis*, *L. spicata* is abundant. All bear very bright, bluish purple flowers, crowded along the upper part of the stem. *L. spicata* has a dense spike of heads, individually smaller than those of the others, but so compact and covering the stem to such a length that its top is a cylindrical mass of bloom, contrasting well with the yellow of the more humble Golden-rods around it. *L. scariosa* bears a similar spike, but it is not generally as long, though the heads are larger, but less closely placed. *L. cylindracea* is the smallest of the three, with a few but prominent heads, having a long, cylindrical involucre. The most symmetrical of them is *L. spicata*; its numerous linear leaves, long near the ground, shorten so gradually that the plant tapers very evenly from the base to the beginning of the spike. *L. scariosa* has the handsomest inflorescence, not only on account of its larger heads and flowers, but its buds, often furnished with bright reddish purple scales. Their season of blooming does not agree throughout. *L. cylindracea* and *L. spicata* begin to flower about the same time, but the latter lasts considerably longer. *L. scariosa* starts later and goes on into October. The first of these is out of flower when the last is at its best, and when the top of the spike of *L. spicata* wears a withered and rusty look. This last feature detracts from the beauty of a *Liatris*, since the mode of inflorescence being from above downward, the withered flowers are more obtrusive than if the heads unfolded the opposite way. This is specially remarked when the spike is long, for a stem ending in buds is more attractive to the eye than one ending in dead flowers, or, in most cases, in fruit. An additional charm is provided for the flowers of *Liatris* on sunny days in autumn, since they are selected almost exclusively for the visits of the large Archippus Butterfly (*Danaüs Archippus*, Fabr.), hundreds of whom are seen flying overhead or lighting on the flowers to sip their nectar, gently opening and closing their many colored wings while busied in this act.

The principal Aster of the early fall is *A. ptarmicoides*. It is exceedingly abundant, and everywhere specks the

dry grounds with white corymbs. A few plants of *Euphorbia corollata* still linger upon the ridges to contribute to this effect, just as earlier in the season they had been equally numerous and effective in whitening the same ridges. Sometimes *A. linearifolius* will be found a common plant on some of the ridges. It reaches about the same height as the former, but is more showy, its larger heads having violet rays. Though each stem commonly bears but a single head, they are apt to obviate their lack of effect in this regard by producing several stems from the same root. Another denizen of the dry grounds is *A. sericeus*. Its heads are large, with rays of violet-blue. Its small but shapely leaves, covered with a silky pubescence, making them as soft as mouse-ears, and its silvery look, render it one of the most elegant of our Asters, though it is a small plant. The three range from one to two feet high. In early fall *A. umbellatus* is common in wetish grounds. Its heads of white flowers, though few-rayed, are quite large, and in sufficient number to make its corymb prominent amid the clumps of low bushes where it most delights to grow. Its elongated leaves, tapering and finely shaped, help to make it an attractive plant. About this time *A. multiflorus* is seen in the dry soils, with small but profuse flowers, rendering it a mass of white. Its grayish stem and leaves give it a well defined appearance. It is not uncommon to find the stems two or three feet high at the time of flowering, bare of leaves below and bushy-branched above, showing little but flowers, the small and scale-like leaves upon the branches buried in the profusion of blossoms. *A. ericoides* has similar heads, but they are more scattered on the branches, so that it is much less effective in appearance. Here it is generally not so stout a plant as *A. multiflorus*, its stems being rarely more than twenty inches high and very slender. It frequents damper and often more grassy situations. In the latter part of the month of September, and on into October, *A. azureus* is one of the most abundant as well as the finest Aster in the Pine-barrens. Its range of ground is considerable, being equally at home in that which is not too moist, as well as in dry ground, in open places and also in those somewhat shaded. It adapts itself to prairies and open woods, though more common in the former. The color of the flowers is quite variable, and consists of all shades from azure blue to violet-purple. In fact, the violet shades often predominate. The stems frequently turn purple, and the leaves sometimes, especially in the full sunlight. It is about three feet high, branching freely and loosely above, bearing medium sized heads, frequently in such quantities as to bend the rather slender stems to one side, nor does it drop its lower leaves as much as many Asters do at the time of flowering; these are so variable in form as to make its identification quite puzzling at times. There are several Asters along the margins of the ponds common and characteristic, such as *A. Tradescanti*, *A. vimineus*, *A. junceus*, flecking the coarse Grasses and Rushes, and the changing leaves of the low shrubs, with spots of pale purple and white. In the course of the fall the Asters will equal or exceed the Golden-rods in variety, coming later into bloom and lasting for a longer time.

Englewood, Chicago.

E. J. Hill.

Plant Notes.

Some Recent Portraits.

The *Gardeners' Chronicle* issued on November 15th contains a figure of *Chrysanthemum Indicum*, made from a specimen collected by Dr. Augustine Henry "on rocks in a mountain of coniferous wood at an elevation of 8,500 feet above the sea-level at Yin-Yü-Ho in the Fang district of Hupeh. The flowers are yellow. At this altitude the plant is very graceful, delicate, and small in stature. It has quite a different aspect from the plant which occurs in ditches and valleys along the banks of the Yang-tse, near Ichang, at levels of under 1,000 feet." This interesting plant is already in cultivation in England from seed collected by Dr. Henry, and although the seedlings have not yet flowered, specimens were exhibited by Mr. Sutton at the Chrysanthemum Conference of the Royal Horticultural Society held in London last month. It is of special interest, inasmuch as it probably represents one of the original wild forms from which the modern garden Chrysanthemum has been derived. According to Dr. Henry's notes, reproduced in the pages of our contemporary, "the Chrysanthemum is known to the Chinese as the Chü-hua; and dried flowers of certain cultivated kinds are much used in medicine and form a considerable article of trade, there being an annual export of eighteen tons from Tientsin, twenty-two tons from Hankow and thirteen tons from Ningpo. The Ningpo variety,

known as Hang-chü, because it comes from the adjacent Hang-chow prefecture, is a yellow-flowered variety and sells at three times the price of the other kinds. The so-called Sweet Chrysanthemum is exported from Canton to the amount of three tons yearly, and the flowers are probably like those of some plant like *Cotula anthemoides*."

Monsieur André, in the issue of the *Revue Horticole* for November 16th, describes, with the aid of an analytical drawing of the flowers and a beautifully colored plate of the fruit here reduced to one-half its natural size, an interesting Brazilian plant of the Cucumber family, *Sicana odorifera*, which has been cultivated by our correspondent, Monsieur Naudin, the great authority on this family, in the garden of the Villa Thuret at Antibes, where the fruit which served for the illustration in the *Revue Horticole* was produced. This fruit, which is bright orange-scarlet in color, narrowly ovate and ten or twelve inches long, is exceptionally ornamental and possesses a penetrating and agreeable odor. It is the Curuba or Curua of the Brazilians, and is used by them to perfume their houses. It is edible, also, when cooked, although the flavor is not agreeable to every one. According to Monsieur André it recalls a combination of mushrooms and apple-marmalade.

The *Sicana* has been known for 150 years to science, having been discovered in 1636 by the German physician, George Marcgraf, who had been sent to Brazil by the Duke of Nassau to explore the coast-region between the Rio Grande and the Pernambuco. Pison, the famous Dutch naturalist, was associated with him in his scientific explorations, and between them they discovered the Curuba and published the first description of it. Later it received from Vallozo the name of *Cucurbita odorifera*, and it was Naudin, with abundant material at his disposal, who was able to discover characters which enabled him to establish his genus *Sicana*.

Sicana odorifera has long remained the only species of the genus. Monsieur André, however, now calls attention to a second species, of which fruit has lately been received in France from Paraguay, and for which he proposes the name of *S. atropurpurea* on account of the dark violet color of the fruit, which resembles in external appearance that of a large egg-plant. The fruit is much larger than that of the Brazilian species; the seeds are larger, longer, rhomboidal and not oval, with the basal appendage oblique. The ripe fruit is also used by the Paraguayans to perfume their dwellings. These two plants, which are perennial, the first with stems extending for a distance of twelve or fifteen feet, can be grown probably in our southern states, where the fruit would prove a conspicuous ornament in gardens.

New or Little Known Plants.

The Pelican-Flower (*Aristolochia grandiflora*).

THE remarkable flower, one of the very largest known, reproduced in the illustrations of the present issue was grown at Bordentown, New Jersey, by Mr. E. D. Sturtevant, who communicates the following note with regard to it:

"About a year ago a wealthy amateur residing on the Hudson River sent me some vines under the name of the 'Duck-plant,' or '*Aristolochia Pelican*.' It was said to be new, and I was unable to find any description of it in the Gardeners' Dictionary or in the catalogue of any nurseryman. Upon inquiry at Kew I was informed that it was not in cultivation there, but that it had been described and figured in the *Botanical Magazine* under the name of *Aristolochia grandiflora* or Pelican-flower. This plant has proved easy of cultivation and rapid in growth with me. In December of last year a young plant was placed in a good sized box of rich soil in a warm greenhouse. This plant in June had made a growth of twenty feet and began flowering. Many buds are now (October 1st) well developed and one is open. At first sight the plant reminds one of a large Morning Glory-vine. The flower-buds, hanging pendent in different stages of growth, form certainly one of the most remarkable sights in the vegetable world, and cannot fail to cause exclamations of wonder from persons seeing them for the first time. The resemblance to the form of a duck or pelican is very close, the head, bill, neck and body being plainly outlined. The fully developed bud measures fifteen to eighteen inches in

length, and is as large as a good sized duck. This is exclusive of the long tail-like appendage. One flower fully expanded last June measured twelve by eighteen inches with forty-two inches of tail, making the total length sixty inches. At the time the bud opens the tail assumes a spiral form and appears to be intended as a ladder for the use of insects seeking to reach the flower. The centre of the flower appears like purple velvet, the inside of the throat being lined with hairs turned downward, and intended, apparently, to prevent the return of the insects caught within. The open flower, unfortunately, emits a fetid and very disagreeable odor, but this is not perceptible before it expands. I find that this plant flourishes in good loam mixed with old manure or other fertilizers. It may be planted out in a warm greenhouse or grown in a tub which can be kept in the open air during the summer and taken in before frost."

*Aristolochia grandiflora** was first described by Swartz in one of his works on the plants of the West Indies published more than a century ago. Patrick Browne found it in Jamaica and published a short account of it in his work on the natural history of that island under the name of *A. scandens*, giving to it the vernacular name of Poison Hog-meat from the reputed poisonous properties of the plant. Tussac, who published an excellent colored plate of the flower, relates that a whole herd of swine had perished from eating the roots and young stems of this plant. Lunan, in the "*Hortus Jamaicensis*," appears to have first given it the appropriate name of Pelican-flower, stating that "the plant is so abominably fetid that it is detested and shunned by most animals; yet when hogs venture by necessity to eat of it, it destroys them."

A. grandiflora is now known to be widely distributed in the West Indies, and extends to Central and South America, where it is by no means rare, occurring along the banks of streams usually in low, rather moist situations. It was introduced into cultivation from seeds sent to Kew from Jamaica by Mr. Purdy. It flowered at Kew in 1848, when excellent figures of the flowers were published in the *Botanical Magazine* and in other periodicals. It appears, however, to have soon disappeared from gardens, and Mr. Sturtevant's plants are the only ones, so far as we have any knowledge of the matter, which have flowered in gardens in recent years.

The figure of the fruit which appears on page 597, the first which has been published, has been prepared from a specimen collected last winter in Guatemala by Mr. John Donnell Smith, of Baltimore, to whom we are indebted for the opportunity to reproduce it.

Foreign Correspondence.

London Letter.

TINTED GLASS.—The behavior of plants when grown under colored glass has been the subject of protracted experiment at Kew. About thirty years ago some of the most important houses were glazed with glass more or less tinted with green, from the belief that this would conduce more to healthy and vigorous growth than the clear glass generally used. The ferneries were glazed with glass several shades deeper in color than the other houses for which green-tinted glass was preferred. Ferns have always been exceptionally numerous at Kew, many of the species being rare and extremely delicate. Probably the value of the collection of Ferns was the reason for the deeper shade of green in the glass used. Evidence which told against the green-tinted glass had gradually accumulated until last year it was decided to replace it with clear glass in a portion of the large tropical fernery, the reconstruction of the roof offering a favorable opportunity for making the change. The result has been most remarkable, the growth made by the plants under the clear glass being much better

than that of the plants under the green. The objection urged against the latter was a practical one—namely, it darkened the house in the winter, when all the light possible was required by the plants, while in summer it did not give sufficient shade to dispense with the use of blinds. Besides this, moreover, many plants also failed to grow under the green glass, although in houses glazed with ordinary glass they were satisfactory. Such were some *Adiantums*, some of the *Gymnogrammes*, *Platycentrums* and others. These plants are now in very fine health in exactly the same positions as they failed in before the glass was changed. Several years ago it was decided to use only clear glass in repairing the other houses. I cannot just now

lay my hands on the reasons advanced by the scientists for the use of green glass in preference to clear, but I believe they were to the effect that the former transmitted exactly the kind of light under the influence of which plants grew best. This light was a sickly green, which, although not displeasing in its effect on the appearance of the plants, gave to the human countenance a peculiarly unpleasant hue.

It has taken nearly thirty years to practically demonstrate the unfitness of green-tinted glass for horticulture, and now these same results have been arrived at by Professor Henslow by scientific experiment. In a paper read at the last meeting of the Linnæan Society the Professor stated the results he had obtained by experimenting on the growth of plants under the influence of glass tinted red, yellow, blue and green, as well as under clear glass and in the open. Of these the green proved not only worse than the clear, but worse even than the red, the yellow or the blue! The best results were obtained from plants grown in the open, which is precisely what every practical man knows must be the case. If the temperature will admit of it, then all plants are better outside than when under glass. The second best results were shown by plants grown under clear glass, and here again practice is at one with the Professor. Blue proved worst after green, then red and then yellow. I have never seen red or blue glass used in horticulture, but what is considered bad glass has a yellowish tint. It all comes to this, then: pure light is best of all for plants, and the next best is that which passes through the medium that least obstructs it—namely, pure clear glass. Of course the intensity of the light is another matter. Horticulturists who use green stipple as a summer roof shade for greenhouses must substitute blinds or a white stipple if they desire to have the best results. This is a matter which deserves attention.

NITRATE OF SODA.—This bids fair to become a most valuable manure in the garden. I have seen it largely used both this year and last for Palms, Pandanads, Cycads, Aroids and other ornamental leaved plants, and invariably the results have been most gratifying. No manure that I have seen used, not even cow manure, in which I have great faith, has produced such immediate effect in the growth, vigor and full color of foliage. Mr. J. J. Willis, writing in the *Gardeners' Chronicle*, maintains that it is a most valuable factor in the production of vegetable crops and fruits. He strongly recommends it for Strawberries, Celery, Cabbages, Onions, in fact for all kitchen-garden produce. But he recommends it to be used in conjunction with ordinary manures. He says: "It may be stated that nitrate of soda is not regarded as a substitute for other manures. Taking horticulture as we find it, we recommend nitrate of soda as the cheapest and best form in which to apply nitrogen to plants. To those who are using ordinary stable manure we say, continue to use it, but use nitrate of soda in addition. . . . With few exceptions, all the fertilizers now generally used, in proportion to the wants of the plants, contain a larger proportion of phosphoric acid, potash, etc., than they do of available nitrogen. If we desire to raise maximum crops, therefore, we must furnish available nitrogen, and the cheapest and best form in which to get this nitrogen is by nitrate of soda." Nitrogen, however, is no more a substitute for other plant food than potash is a substitute for nitrogen.

Another Year Among Grapes.

THE grape season of 1890 proved no more satisfactory in any important feature than the two preceding ones. The variations in different vineyards but a few miles apart in the behavior of the same variety have been remarkable, and were probably due to the condition of the vines at certain stages of the weather. The Rosebug, which devastated the vineyards of south Jersey, has not yet proved serious here, though the number on my vines this year was twice as large as it was last year; but my practice is to kill every one found, if possible, which will, I hope, tend to postpone an invasion against which I shall be powerless. Aside from the leaf-roller, I have had less trouble with insects than usual. Frequent rains and dull weather at the time of blooming did more harm perhaps than any other cause. To this I attribute the imperfect fertilization of the flowers, which exceeded all past experience. A friend but a few miles distant reports his Concords exceptionally good, while mine were never a more complete failure. My theory for this difference is that a few days' difference in their blooming season gave to one vineyard good weather for pollination and bad weather to the other.

Fungi, as usual, were abundant, but bagging heads off the rot, if applied early enough; and spraying with sulphate of copper, has kept the mildew in check, so that damage from these sources has been inconsiderable. We now fear these enemies much less than heretofore, but an old, and as yet unconquerable, foe made an invasion which brought more widespread ruin than our vines ever before suffered. This is the Anthracnose, a Fungus that attacks the young growth of the Vine as well as the fruit. In slight attacks the young cane is only discolored, and they partially outgrow the disease, but seldom, if ever, fully recover. In this stage many persons would not recognize it. A grape-grower of long experience visited me this season, and he could hardly be persuaded this was an early stage of the contagion. He only recognized it after it had developed and ruptured the tissues of the bark, showing its black spots, and had stunted or killed the young canes. As yet no certain remedy for this Fungus has been found. This disease should be a subject of experiment by our scientific students and practical grape-growers, and an effectual remedy will be as welcome as was the cure for mildew.

The labor of combating insects and these Fungi, together with low prices for the fruit, renders grape growing for profit less enticing than formerly, and where all of these difficulties

abound it is not strange that some growers are abandoning the business. When we consider that some varieties are much more liable to fungous attacks than others, it is a debatable question whether they are not more likely to appear and more virulent when they do come in vineyards containing a large number of varieties than where there are fewer. The test of a Vine's resistant qualities among a large number of varieties would be more satisfactory than if it were planted by itself.

The Vine-grower has other trials than those arising from insects and plant diseases. He must study the public taste, and the consequent demands of the market. A grape good enough for me to eat is good enough to sell, but among more than fifty varieties I find some I could not put in either class, although they are highly extolled in other sections. I add some notes on the relative value of different varieties according to my experience.

To commence with, Moore's Early, among the black Grapes, is of fair quality and size, but not very productive. It is followed by Cottage, a more vigorous and productive variety, and equal to it, if not better, in quality. Then comes Worden, larger and better than all. If it only had the skin of the Rogers' Hybrids it would be about perfection in its line. Concord, belonging to this class, will have to follow here, though with the purchasing public ninety-nine out of every hundred, and many dealers as well, regard all black grapes as Concords, and buy and sell them as such. About the same proportion of the public know but two pears, Bartlett and Seckel, and call for them at all unseasonable times. Of other black grapes that will keep longer and are better in quality, I name Wilder (Rogers' 4), Aminia (39), Barry (43), Herbert (44) and Merrimac (19), in the order named.

Of red grapes, Brighton is early and excellent, but liable to set poorly; Lindley (Rogers' 9) is open to the same objection, and so is Rogers' 32. A vine or two of Delaware I keep for its intrinsic excellence, and Berckmans will probably prove an acceptable substitute. Among the Rogers' Hybrids there is much confusion. The

Aminia was so named by Mr. Bush, of Missouri, because it was one of two varieties received under the same number. I have two distinct varieties, both received as No. 32, and it is not an unusual thing to get two or three kinds in an order of twenty-five vines of the same variety, though obtained from the most reliable sources. Some of these hybrids so closely resemble each other that an error of this kind would easily escape detection among the black kinds, but when some of these turn out to be red ones the mistake is pretty palpable.

Among white grapes Niagara far surpasses all the rest. Pocklington rots and cracks badly and is too foxy. Martha is a poor apology for a grape, though the vine is vigorous and

Fig. 79.—Side View of a Flower of *Aristolochia grandiflora*, much reduced.—See page 596.

hardy. The clusters and berry are both small. The Lady is larger in berry, earlier and much better in quality, but the vine is a slow grower and unproductive, the clusters are small, and the berries crack and rot as soon as ripe. Lady Washington,

goes also. How it can be so highly extolled as it is by some good men I cannot conceive, unless it is altogether a different Grape with them from what it is with me. To look at the vine in wood and foliage it appears to be wild enough to deserve the

Fig. 80.—A Flower of *Aristolochia grandiflora*, much reduced.—See page 596.

with thinning and extra care, might give some satisfaction. Prentiss is too uncertain. Elvira, Pearl, Grein's Golden and Missouri Riessling are too poor for table use, although they may answer for wine in the west, but with me they are marked for grafting another season if possible. Noah, Jefferson and several others are to share the same fate. Woodruff Red

name of iron-clad. It is productive, too; the clusters are of medium size and very compact, the berries are large, but they rot and crack before ripening, so that often half of them are wasted, and when they do ripen they are but little better than the Champion. Of a dozen vines I have, all but one or two are to be grafted with better sorts. Another highly commended

variety, Early Victor, is about as near worthless with me as any of the list. The vines are vigorous and healthy enough, and the grape itself is good, but the cluster and berry are too small. In this respect it falls below the Delaware, and anything below or equalling that in size must be of superior excellence to become popular.

Of recent introduction, Munson's Brilliant is among the promising red ones. The cluster and berry are of good size, and the quality seems up to the standard.

Montclair, N. J.

E. Williams.

Tritonias.

THOUGH the Tritonias are less graceful than the Ixias and less brilliant than the Sparaxis, they are, I think, the most desirable for general cultivation of the smaller Cape bulbs. They are more vigorous than the Ixias, and never, like them, damp off when half grown. They lack the vivid contrast of scarlet, yellow and black with which some kinds of Sparaxis dazzle us, but they will give three flowers for every one Sparaxis yield, and these are quite showy enough, ranging from vivid orange-crimson to pure white. With Ixia and Sparaxis failure is fully as probable as success, but with Tritonia no one need miss a bountiful supply of flowers.

As in other genera of the Iris family, there is much confusion as to the species of Tritonia; probably more than half of those who have *T. crocata* call it the orange Ixia, while other sorts have been ranked with *Gladiolus*, *Montbretia*, etc. It is to be hoped that Mr. Baker's long-promised work on this family will soon be issued, so that we may have an authoritative guide. I have cultivated many of the species of this genus, and find most of them to vary much from seed without hybridizing, which, all will agree, adds a new charm to a plant, for no one will dispute as to the pleasure with which we see a new flower unfold whose counterpart no one has ever beheld. Some of these are so lovely that I shall name a few of them after speaking of the species as far as I have knowledge of them.

T. crocata is the best known of all, and, with its spike of brilliant orange flowers nearly two inches across, is showy enough to suit the most exacting. Like the other kinds it is excellent for cutting, as all buds will open, one by one, in a vase of water; this kind looks particularly bright and attractive by artificial light. *T. miniata* and *T. deusta* differ but little, horticulturally speaking, from *T. crocata*. *T. hyalina* of Linnæus is generally found in the Dutch catalogues under the name of *T. fenestrata*, given to it by Jacquin. Both names are applicable, and have reference to the fact that, at the base of the segments, color is lacking, and the tissues are transparent like windows. The general color of this species is lighter in shade than that of the other kinds. *T. squalida* is a very beautiful sort; its color is white, shaded at the tips with rose. This is regarded as a distinct species by all the botanists, and distinct it must therefore be, yet I have repeatedly raised it from pure seed of *T. crocata*. *T. scillaris* is less vigorous than the other species, but is very beautiful, bearing numerous bright rosy flowers, which, however, are much smaller than those of other kinds.

The plant called by some *T. aurea*, and by others *Crocisma aurea*, may as well be mentioned in this place. It is probably well known to nearly everybody; but, for the benefit of a possible few, I may say that it is a summer blooming kind, best treated as we treat *Gladiolus*. *Aurea* is a singularly inappropriate adjective to apply to its deep orange blossoms. It makes its new corms at the end of underground runners several inches long. When the bulbs are lifted they will be found to have more or less of these runners, without any bulbs at the end, but looking much like the pestiferous Witch Grass. These ought by no means to be removed, for they will retain their vitality until planting-time, and will then go on without delay, whereas had they been cut off there could have been no blossoms except from the old corm until new runners had grown, which would have shortened the flowering term two or three weeks. It is commonly said that in the autumn, when we lift the corms, the old ones, those we planted in the spring, ought to be discarded because they will never grow again. This is an error; they will grow again, but their growth will be comparatively unproductive of flowers. There are two varieties of this plant, *Maculata*, which, I believe, grows wild in Caffraria, and *Imperialis*, which we owe to the zeal of Mr. Max Leichtlin, or, rather, shall owe, when it is generally distributed.

T. crocata varies in its wild state, four or five well marked varieties being recognized by botanists. It varies even more in cultivation, some of the best sorts being Copper Chief, a very strong growing variety of a coppery red; Lady Rose, pink salmon ground, flecked with crimson; *Maculata*, flesh color,

with deep crimson centre; Rubens, white, with carmine centre; Striata, pink segments, with median stripes of scarlet; Brenda, beautiful shade between rose and salmon; Bellala, segments alternately flesh color and scarlet; Hermosa, bright rose centre with salmon scarlet tips; Galatea, white, flecked and marbled with light purple; Fuego, fiery scarlet; Peach Bloom; Fenestrata speciosa, very light buff, externally light orange. Many others might be named, but enough has been said to show between what limits the colors may vary and to give an idea of the desirability of the genus. Some years ago I hybridized the white form of *Freesia refracta* and *Tritonia crocata*. Singularly enough the resulting plants bore flowers which were *Freesia* pure and simple, though the *Tritonia* was the seed parent.

Cattleya maxima.

THIS species, although by no means common, is nevertheless frequently seen in collections. It flowers from October to November, and is a fitting companion for the late flowering forms of *Cattleya labiata*. The pseudo-bulbs are more or less club-shaped and compressed, varying in length from six inches to two feet, and are furnished with a single oblong leathery leaf six to twelve inches long and about two inches broad. Some specimens are now flowering in the collection of Mr. R. H. Measures, of Streatham, bearing two or three flowers on a peduncle which springs from the top of the pseudo-bulb, enveloped at the base by a large sheath. I remember, however, seeing several plants in bloom in October of last year, and some of the peduncles had as many as ten large flowers on them. The lanceolate-acuminate sepals and the much broader, oval-oblong, wavy petals are of a beautiful satiny rose color, through which the netting of the veins may be seen, thus adding a further adornment to their appearance. The lip is tubular, much crisped at the edges, and having the same ground color as the sepals and petals, but beautifully marked with a network of deep, rich purple lines, which are closely arranged on each side of the bright yellow band, which extends down the throat and is very conspicuous.

For more than a hundred years *Cattleya maxima* has been known to scientists through the labors of Ruiz and Pavon, two Spanish botanists, who first met with it near Guayaquil, on the Andes of Peru, about the year 1777. It was not, however, until 1842 that *C. maxima* found its way alive into Europe. This was accomplished by the Royal Horticultural Society, who had sent their collector, Theodor Hartweg, out to South America in search of new plants. He first met with *C. maxima* near the banks of the Rio Grande de Melacatos, in Ecuador, where it was growing on rocks and trunks of trees. Plants were sent home, and the first flowers appeared in the Society's gardens at Chiswick in the year 1844. From this time until 1855 no trace of the plant is to be found until a pale-flowered form appeared in the collection of Mr. W. G. Farmer, of Nonsuch Park, Cheam, Surrey, and formed material for a figure in the *Botanical Magazine*. Since this period, thanks to the importations of Veitch, Backhouse, Low, Sander and others, *C. maxima* has become an established plant.

There are a few varieties known, such as Alba, having white flowers with purple reticulations on the lip on each side of the median yellow band; Aphlebia, rarely seen, and characterized by the absence of the purple lines on the lip; the variety Peruviana, commonly spoken of in gardens, which comes from Peru, and is noted for its deeper colored flowers, with more numerous and darker lines on the lip.

The cultivation of *C. maxima* (which, by the way, the late Professor Reichenbach once called an *Epidendrum*) is not difficult. The plants like a warm, moist house, such as *Dendrobiums* grow in, and will thrive in the usual compost of rough peat and sphagnum in well drained pots. They begin to grow in the autumn, at the same time as the flowers are borne on the previous year's pseudo-bulbs, and will consequently require attention as to watering during the winter months. According as the new growths appear, and the new roots begin to push through the soil, the quantity of water may be correspondingly increased. In the summer, when the growths are ripening, as much light and air as is consistent with safety should be given, so as to have the plants thoroughly mature by the autumn.

Isleworth, London.

John Weathers.

Lonicera quinquelocularis, a native of northern India and the Himalayas, can hardly be called a highly ornamental plant when there are so many others possessing greater merit; but it is interesting on account of the profusion of fresh, clear, almost transparent fruit which it bears in the late autumn

long after the leaves have fallen. It is the only hardy bush Honeysuckle here which ripens and retains its fruit in perfect condition so late in the season. The black seeds are plainly visible within the pulp, which is somewhat mucilaginous and disagreeably bitter to the taste. The pubescent, ovate, pointed leaves are from one to two inches in length, and the flowers are small and of a light yellowish white color. In well drained and moderately sheltered situations the plants are quite hardy in this latitude, and may grow as large as the more showy flowering Tartarian Honeysuckle.

Among the climbing Honeysuckles the shining black fruit of the popular Japanese species (*L. Japonica*) is too much hidden by the evergreen foliage to be conspicuously ornamental, but at this date (November 27th) a large proportion of the fruit of *L. Sullivanti* is still full and fresh looking and of a bright red color. No other climbing deciduous species appears to keep its fruit in a fresh state so late in the season.

Correspondence.

Early Chrysanthemums.

To the Editor of GARDEN AND FOREST:

Sir.—It is true, as Mr. Thorpe states in his reply to my note on September Chrysanthemums, that they will continue to be grown, but even his well known passion for these flowers does not seemingly lead him to claim much beauty for the varieties which we at present possess. It is gratifying, however, to be assured from such an authority that advances are being made in this class of plants. Some of Mr. Thorpe's early flowers were very promising this year, but only renewed tests and propagation (seemingly one of the greatest trials) will prove their value. Skillful hybridizers like Mr. Thorpe have secrets beyond the ordinary grower, and yet it is difficult to understand how varieties of which M. E. Nichols is the type are to be hastened into bloom a whole month earlier than their natural season. As a type they seem to lack the very early maturation which, with quick bud development, brings Madame Desgranges into bloom so early. The mid-season kinds seem to differ from the November ones only in the quicker development of buds, as both classes of plants form buds at same time usually.

It is hardly a legitimate occasion for criticism that any one finds pleasure in growing any flowers at any season, but, speaking for myself, Chrysanthemums are flowers to be enjoyed only in their proper character and relations. To me Chrysanthemum means profusion of bloom and great masses of color, and these, I find, can only be fully enjoyed in late October and onward. As a fancier I can appreciate flowers at any time; as the owner of a garden I find my greatest pleasures in the blooming of my flowers in their normal seasons. In a well stocked garden one instinctively separates the seasons on certain shifting lines. Certainly the emotions awakened by flowers at one season are entirely different from those produced at others. The Chrysanthemums are glorious on a frosty morning; they seem brighter and firmer in the keen air, and my pulse always beats faster, and it is always with pleasant excitement that I go among them then, to enjoy the masses of bloom and inhale their camphorous odor. What an antithesis to the earliest flowers of spring, whose sudden awakening, stimulated by the first warm rays of the sun, must, even to the most unemotional, bring a pleasure at once exquisite and sober as the mysterious forces of reviving nature are made evident! As the seasons advance the reflective gardener has with each a different set of emotions gratified. To paraphrase Mr. Warner, the gardener needs all the consolations of these pleasures.

Elizabeth, N. J.

J. N. Gerard.

Cycles of Fruit Growing.

To the Editor of GARDEN AND FOREST:

Sir.—The culture of the sour Cherries has greatly declined in the older sections of America. The cause was the prevalence of black knot. This disease has now almost entirely disappeared, and there is no reason why there should not again be a great planting of this most wholesome fruit. If only a few trees are set by scattered cultivators there will be no fruit saved from the birds. There should be a special movement on the part of nurserymen to encourage Cherry-planting. The sorts most advantageous for the general grower covering all the northern states are the Early Richmond, the Mayduke, the large Montmorency, and the common sour Cherry, from which the Richmond and Montmorency have been improved. These are entirely hardy, and could well be grown for their beauty in blossoming season. Percival Lowell's description of Cherry

worship in Corea and Japan is peculiarly fascinating. These Orientals go out in crowds at the time of Cherry blossoms, and also in Plum season, and, sitting under the trees, sip tea, write poems and become as sentimental as lovers. But aside from the flowers, the beauty of the fruit is beyond that of any other tree, and there is none more wholesome.

The time of depression for the Quince is also about over. Forty years ago it was grown very largely in the northern states. Then the borer attacked the trees and whole orchards were obliterated. The cutting of forests also made our climate subject to sharper changes, which made more protection needful for semi-tender fruits. For the last thirty years Quince-growing has been confined to a few localities. Prices have ruled very high, so that a good acre of Quinces will realize profits beyond any other fruit. Seven dollars a barrel has been the average price of first-rate quinces in this market. But the borer is gone or nearly gone; and we know how to prevent his ravages. Now, there is common sense in a general planting of this fruit once more. The requisites of success are a southern or south-eastern exposure, and protection, natural or artificial, against the north-west winds. I always bind my trees with stalks, straw or hay while young and keep them well mulched. A Quince-tree to thrive must be well fed, but not over-fed. Use coal ashes abundantly about the trees.

Another fruit that should come back about now is the currant. I think that in proportion to the population we do not have half the currants that were grown in 1850. The twig-borer is gone, and the currant worm is very easily managed by two sprinklings of hellebore. The market for this delightful fruit is never overstocked.

When I was a boy there were four fruits specially abundant: plums, currants, cherries and quinces. No one imagined they could get on without them. They had their cycle of growth, then a cycle of decadence; now we may replant. The plum is already finding its old place, but the quince, cherry and currant are scarce. Our only chance of successful competition with birds and insects is to plant enough for both the birds and ourselves and together whip the insects. We cannot succeed without an alliance with our friends in the air. The probability of their multiplying beyond reasonable numbers is very slight, except in such an abnormal case as the English sparrow; but we must furnish them food.

Clinton, N. Y.

E. P. Powell.

The Forest.

Systematic Timber-cutting in Quebec.

THE following remarks are translated and condensed from a paper presented in French to the American Forestry Association at its meeting of September 2d, 1890, by Mr. J. X. Pirrault, Secretary of the Quebec Forest-Association:

Now while the destruction of the state forests is carried on so systematically that it is possible to foretell the fatal moment when the province of Quebec will be stripped of its most valuable forest-trees, it is a public duty to make a last appeal to the patriotism of the men who govern us to put an end to the vandalism of which we are every day the witnesses.

For more than a century the public domain has been pillaged with the thoughtless consent of the state. What was once the finest forest-property in the world has been ruined by pasturage, and by the wasteful methods of lumbermen who, not content to make enormous fortunes at the expense of the Province, have cut and destroyed everything in their path without thought of the future.

Our neighbors in the United States have acted with the same want of forethought, but with this difference, that with a population ten times larger than ours the destruction of their forests has gone on more rapidly. Never, perhaps, in the history of any people has there been seen the administration of a public domain so criminal and so disastrous.

The forests of the United States, from the Atlantic to the Pacific and from the frontiers of Mexico to those of Canada, cover 450,000,000 acres. The annual cutting over of 25,000,000 acres gives on an average 4,800,000,000 cubic feet of lumber. The railroads use, in addition, 500,000,000 feet, the mines 150,000,000, fences consume 500,000,000; 150,000,000 feet are exported, while 18,000,000,000 feet are consumed as fuel. The whole forms the enormous total of 24,000,000,000 feet, of an approximate value of \$1,000,000,000—that is to say, more than the total value of the crop of wheat, rye, oats, potatoes, cotton and tobacco produced in the United States, and thirty-three per cent. more than the value of all exportations of every kind from that great country.

It is hardly conceivable and yet it is true that no forest-administration has been charged with securing intelligent

management of this colossal property. It has been truly said that the real riches of a country are not in its deposits of the precious metals, but in its forests, and yet, thanks to the folly of the Government of the United States, these fruitful sources of public wealth have been allowed to perish without any thought beyond the morrow.

Some idea of the enormous traffic which springs from forests of the United States may be gathered, perhaps, from the fact that in Chicago alone the 2,000,000,000 feet of wood and lumber which are handled in that market represent 1,000-car-loads for every working day in the year. If all the forest-products of the United States were moved by rail, we should have a train equal in length to eleven times the circle of the globe at the point of its greatest diameter. The northern states alone produce two-thirds of this lumber each year, or about 20,000,000,000 feet, worth three hundred millions of dollars. This represents a weight of 500,000,000 tons, and would require a fleet of 500,000 vessels, each of 1,000 tons burden, to transport it—that is, a tonnage equal to twice the fleets of the entire world.

This forest-wealth of the United States has been so used and abused that already the richest forests have disappeared. The pine of Michigan, Wisconsin and Minnesota, once considered inexhaustible, exist no longer. They have been exterminated; and this is readily understood when it is remembered that a single mill in this region has cut half a million feet a day, and that the capacity of all the mills of the United States is more than 60,000,000,000 feet a year. According to the Census report, there were in 1880 55,175,000,000 feet of pine standing. Since that time 45,475,000,000 have been cut, so that in all the northern part of the United States there is now only two years' supply of white pine of the best quality left, with more or less pine of inferior quality.

The improvidence of the Government, and the insatiable desire to grow rich rapidly, have brought our neighbors' forests into this condition. It seems almost incomprehensible that a nation so intelligent and practical can allow itself to be despoiled of one of the principal sources of national wealth while it was so easy to render it perpetually productive.

And what have we done ourselves here in Canada? Have we not committed the same blunders? Has not our public domain been pillaged also? How many millions have been sent from Canada during the last fifty years to enrich the people of London? Our Pine-forests have nearly disappeared. The timber of which we were once so proud has vanished. The pine, which is now found only between the Red River at the west and Migen at the east, does not extend north of the forty-ninth degree of latitude in the valley of the Ottawa and the fifty-second degree in the region of Albany Lake. There is none north of Lake Superior. Our best Pine-forests were in the valleys of the Ottawa, of the San Maurice, of the Saginaw and their tributaries. All these have been destroyed, and now it is necessary to go 300 miles from Ottawa to the headwaters of the San Maurice and to Lake St. John to find lumbermen at work. All that immense forest-territory of the province of Quebec, of more than 100,000 square miles area, would represent to-day hundreds of millions if the state had managed it intelligently. But here, as in the United States, every one supposed our forests were inexhaustible. They have been cut without pity and without rest.

The Government was deaf to every appeal to protect the public forests as long as a few hundred thousand dollars, derived from the forest, was available to make up the deficit of the general administration. The sale of limits made often to political partisans, most often fraudulently and at prices absolutely ridiculous, have almost entirely ruined our forests. Great bodies of timber have been sacrificed at ridiculous prices in time of panic when there was no demand for timber. In 1844 the Government, among other limits, sold one of 100 square miles for \$4 a square mile—that is to say, at the rate of two acres for one cent. Is it possible to imagine any greater folly in the administration of Government affairs? The results of these wasteful methods are apparent. The cut of pine east of Montreal, which amounted two years ago to 250,000,000 feet, has now fallen to 25,000,000—that is to say, to an annual output of only ten per cent. of the former production—and this for the excellent reason that there is no more pine to cut in that region. It is the price of the ruin of the forest-capital of the province which the government of Quebec has received and still receives every year. We have obtained as a gift from our fathers a forest-domain unequaled in the world. It was able every year to produce an enormous revenue, sufficient, if properly administered, to meet all the expenses of the state. And we have not been sufficiently intelligent to administer this property in such a way as to perpetuate the revenue for

our children. On the contrary, without regard to the most elementary rules of forest-culture, we have alienated the forest-domain by throwing it open to a crowd of greedy speculators whose only other aim has been to destroy it entirely. Such criminal conduct merits the contempt and reproof of the whole world. The province of Quebec is not alone culpable. Ontario, New Brunswick, Newfoundland are even worse off than we are, and when the forest-resources of the Canadian confederation are examined, it is only too apparent that in a comparatively short time we shall be obliged to depend for our timber upon other provinces. British Columbia, on the Pacific side of the continent, is well wooded, but her forests are too remote to be of practical value to us here in the east. The timber supply of British Columbia will be needed by her own people and by those of the north-west. Her timber can be sent to Australia, California and South America more advantageously than to us here. From the Rocky Mountains to Lake Superior timber is scarce. It is disappearing rapidly in Ontario; and in the maritime provinces and in all the eastern counties consumption is increasing and the supply is disappearing very rapidly.

It is evident, then, that the province of Quebec must adopt at once the methods which are everywhere recognized as necessary to stop this destruction and assure by means of an intelligent administration the perpetuity of what remains of our forest-domain. It is necessary, in a word, to inaugurate here a system of regular cutting such as is practiced in France, Germany and other civilized countries, where not only the annual output is preserved, but the extent and value of the forests are steadily increased. The government of Quebec should, in order to preserve its forest-domain and increase for all time its productive capacity, adopt the following plan:

First. It should divide the public domain into five great forest-regions—namely, Ottawa, San Maurice, Saginaw, the counties of the east and the Gaspasie—and place each under the direction of a general forest-officer. Each of these forest-officers should then divide his region into as many forests as there are distinct regions, each composing a certain number of limits.

Each forest should be worked, under the direction of a forest-officer of the region, by a timber-merchant, owner of a saw-mill, and such a forest should be cut once in every twenty years or more, according to the nature of the soil and the trees which are found in it. In this way every year a twentieth part only of the forest would be worked; the remaining ninety-five per cent. will be left to its natural growth and protected against all inroads from the lumberman or his employees. By cutting each year trees only which have arrived at their full value, those preserved would be ready for the axe twenty years after. In this way a forest will perpetuate itself indefinitely, yielding constantly an equal and regular annual product without deterioration.

Second. Every year the Government should determine what will be the amount of timber called for by the needs of commerce in order to avoid the over-stocking of the market and the commercial disasters which result from over-production and the consequent shrinking in value of forest-products.

Third. As is well known, the squaring of timber in the woods, by which the soil is covered with chips, is an imminent cause of fire, and a third of the wood moreover is lost by this means. The Government should demand that all trees should be sawed, not hewn, or floated down the streams in convenient lengths to points of shipment.

Fourth. The Government should exercise an intelligent inspection over the operations of lumbermen, and it should be the duty of the general forest-guards of each region to mark themselves, or to have marked by their assistants, all trees to be cut or to be reserved in the annual cutting.

Fifth. The Government should send to the Forest-School at Nancy a certain number of young men who, having followed the course there in forest-studies, would be fitted later to assume the direction of our woods and forests.

Sixth. As the management of our woods and forests belongs to the department of the Minister of Agriculture, the general forest-guards should be placed under the direction of that officer in all matters relating to the valuation and exploitation of the forest-domain.

It will perhaps be argued that these indispensable forms will entail serious expenses on the Government. This is a mistake. It is simply a redistribution of duties and a transfer of the Government employees, which is necessary in order to put this system in operation.

And after all, a forest-domain of 50,000 square miles is well worth the trouble and expense of some attention. It produces

annually something like 400,000,000 feet of pine and 110,000,000 feet of spruce, besides 37,000,000 feet of red and white pine timber, 600,000 feet of hard wood, 4,500,000 railway ties, besides vast quantities of cedar, tamarack and 5,000,000 feet of fire-wood; the whole producing a revenue to the province of a million dollars. The total annual forest-product for all Canada amounts to \$25,000,000, and this will double certainly as wood becomes rarer in the United States. In a few years from now the province of Quebec will obtain from her forests a revenue sufficient nearly to meet all her expenses, provided an intelligent forest-administration can be established. We still have in our forests and in our waste land hundreds of millions of dollars with which can be assured the greatest prosperity of the province, but it is necessary that the men who govern us should realize the urgent necessity of administering wisely this magnificent inheritance upon which depends the future prosperity of the nation. And especially is it necessary that they consider the rights of the coming generation and determine to protect this inheritance against the attacks of the short-sighted and thoughtless.

North American Fauna. No. 3. Results of a Biological Survey of the San Francisco Mountain Region and Desert of the Little Colorado, Arizona. By C. Hart Merriam, M.D., United States Department of Agriculture, Division of Ornithology and Mammalogy. Washington, 1890.

This is the outcome of a careful biological study of the San Francisco-mountain region of Arizona, and although Dr. Merriam's studies are principally devoted to vertebrate animals, his paper contains much which is of direct interest to botanists, but interesting as it is, the results, as has been well pointed out in the *Botanical Gazette*, are specially "valuable in that they mark out a line of botanical work which the Government should at once enter upon and push to its completion."

Dr. Merriam deals with the general subject of geographical distribution, and the conclusions which he reaches are, that there are two life areas in North America, a boreal and a subtropical, both extending across the continent with long interpenetrating arms. He abandons therefore the three life areas generally accepted by naturalists—namely, an eastern, a central and western—establishing, however, in the particular region discussed seven lesser life zones, four of northern and three of southern or mixed origin. The correlation of the northern zones with corresponding zones in the north and east are pointed out.

Dr. Merriam first treats of the Alpine zone, which embraces the bleak and storm-beaten summit of San Francisco Mountain, which rises to an elevation of 11,500 feet. Nine of the species of plants growing here were collected by Greeley on the shores of Lady Franklin Bay, and many of them are found scattered over the mountain ranges in all the northern parts of the continent. It appears "that many of the plants found on the high rocky summits of San Francisco Mountain occur on the higher peaks of the Rocky Mountains, the Sierra Nevada and Cascade range, and the Appalachian chain. They occur along the arctic coasts of Alaska, Hudson Strait, north Labrador, Greenland, north Siberia and Spitzbergen; they occur in the Alps of Europe, in the Altai and Ural Mountains, the Pyrenees, and some of them even in the Himalayas. In brief, they inhabit the arctic regions of the globe and extend far south on the summits of the higher mountain ranges. Plants and animals having such a distribution are termed Arctic-Alpine Circumpolar species."

"Just below the barren arctic summit of the mountain is a narrow belt which may be named the Timber-line zone. Here the trees which reach timber-line (in this case *Picea Engelmanni* and *Pinus aristata*) lose the upright or arborescent habit and exist as stunted and prostrate trunks, whose gnarled and weather-beaten forms bear testimony to the severity of their struggle with the elements. In this narrow belt a number of hardy little plants attain their maximum development, decreasing rapidly in abundance both above and below. Many of them are circumpolar species found throughout the northern regions of America, and some of them throughout the northern regions of the world, coming south on high mountains, and occurring in greatest perfection just at or near the edge of the northern limit of trees, and at timber-line on mountains further south. Such plants are known to botanists as 'sub-Alpine' species, and it would be well if the term sub-Alpine were restricted to the characteristic species of this zone."

"Passing down into the next zone, the Spruce-zone, a num-

ber of plants, birds and mammals are encountered which are characteristic of humid northern regions, but regions not quite so cold as those inhabited by the species which occur on the snowy summit and at timber-line. The characteristic trees of this zone are Engelmann's Spruce (*Picea Engelmanni*) and the Fox-tail Pine (*Pinus aristata*). The fact of present interest is that many of the plants here enumerated as growing in the Spruce-zone of this mountain are equally characteristic of the upper Spruce-belt of the higher Alleghanies, the Rocky Mountains, the Cascades and the Sierra Nevada, and occur also in the great northern Spruce-forest of Canada. It is well known that the northernmost part of our continent consists of bare rock and frozen tundras. There are no trees along the sea edge of Labrador or Hudson Strait, or along the coast region of arctic America from Boothia Felix to Alaska, but just south of this region a large forest begins which has been called the Great Pine Forest. There is not a Pine-tree in it, but it is called Pine because conifers in general are called Pines by people who are not botanists. The tree that grows there is a species of Spruce congeneric with the Spruce which occurs high up on San Francisco Mountain, and many of the humbler plants are either identical or closely related representative forms."

"The distinctive tree," of what Dr. Merriam calls the Canadian or Balsam Fir-zone, "is the Douglas Fir (*Pseudotsuga taxifolia*), which ranges northward to British Columbia. Another tree of nearly coincident vertical distribution on the mountain is the lofty Rocky Mountain Pine (*Pinus flexilis macrocarpa*), which extends north to the Kootenai region and Calgary, in Canada. Wherever the Douglas Fir has been burned off its place is taken by the Aspen (*Populus tremuloides*), a species of wide distribution in the north, where it ranges from New England to Newfoundland and Labrador, and thence westward to Alaska, reaching its highest perfection along the southern part of the great coniferous forest of northern Canada, and coming south in the mountains." In this belt Dr. Merriam found such plants as *Geum triflorum*, *Potentilla fruticosa*, *Actæa spicata* and *Viola Canadensis*, all of wide distribution in our north-eastern flora, as well as a *Ceanothus* representing a western-American genus, with two species penetrating into our eastern flora.

The next natural division is called by Dr. Merriam the Neutral or Pine-zone. "The characteristic and only tree of the Pine-zone is *Pinus ponderosa*, which forms an unbroken forest over the whole of the lava plateau above the altitude of 7,000 feet, and extends up as high in some of the parks as 8,800 feet. As a distinctive species, however, it loses its character at about 8,200 feet, where it is invaded and soon after replaced by *Pinus flexilis*, *Pseudotsuga taxifolia* and *Populus tremuloides*. *Pinus ponderosa* may be regarded as a tree of the middle elevations, occurring between the Piñon and Cedar of the lower hills and the Firs and Spruces of the higher mountains. In such situations it ranges from the highlands of western Texas and northern Mexico, northward along the Rocky Mountains and Sierra Nevada to the dry interior of British Columbia, in latitude fifty-one degrees thirty minutes, avoiding the region of excessive rainfall along the coast from northern California northward."

Next below is the Piñon-zone:

"The distinctive trees of this zone (6,000-7,000 feet) are the Piñon or Nut Pine (*Pinus edulis*) and the so-called 'Cedar' (*Juniperus occidentalis monosperma*), both averaging about sixteen feet in height. The singular checker-bark Juniper (*Juniperus pachyphloea*), a very handsome and conspicuous species, occurs in two or three special localities, but is rare. Several large shrubs not observed elsewhere are abundant in parts of this belt, namely, *Berberis Fremontii*, *Rhus aromatica*, var. *trilobata*, and *Spiræa discolor*, var. *dumosa*. Both the Piñon and Cedar occupy elevations of corresponding temperature in the arid lands from western Texas through New Mexico and Arizona and northward to central Colorado, and the Cedar reaches westward to southern California. Closely related and strictly representative forms extend northward through the Great Basin to the Plains of the Columbia. The other species mentioned occupy more or less of the same range, and some of them push northward over the Great Plains as well as the interior basin."

Space will not permit us to reproduce Dr. Merriam's account of the desert of the Little Colorado, the so-called "Painted Desert" of the earlier explorers, which he crossed and recrossed several times. The extracts we have laid before our readers are sufficient, however, to call attention to the importance and interest of this publication, which is by far the most considerable contribution to our knowledge of the plants and animals of a peculiarly interesting region which has yet appeared.

Notes.

The Massachusetts Horticultural Society will offer \$3,800 next year in prizes for flowers and plants.

Fifty-six Chrysanthemum shows in as many towns and cities have been reported so far this year in the *American Florist*.

The death is announced of the German landscape-gardener, Niepraschk, the author of many important parks and gardens in different parts of Germany, and in recent years Director of the Garden of Flora at Cologne.

Not less than \$1,600 was taken from the sale of tickets to the Chrysanthemum exhibition recently held in Boston by the Massachusetts Horticultural Society. Financially this was one of the most successful exhibitions ever given by this Society, the receipts being double those of last year at the corresponding exhibition.

Pierre Tschihatheff, the distinguished traveler and naturalist, has recently died in Florence. He is known by his French translation of Grisebach's "Vegetation der Erde," which he enriched with many original notes, and by his great work on the natural history of Asia Minor. It was for him that the Pyrethrum, now used successfully in dry countries to form turf in the place of grass, was named.

Our figures of the *Aristolochia* this week will recall the interest which was excited by the flowering in Kew last spring of *Aristolochia Goldieana*. The plant was described as so small that it could be crumpled in a man's hand, while the great white-tubed flower was too large to conceal in a peck measure. The interior of the flower was strangely beautiful, too, with its pencilings of purplish chocolate on a ground of old gold. *Aristolochia longicauda*, mentioned last week, is one of the most distinct and handsome of the unilabiate group.

Tuberous Begonias, Herbaceous Pæonies and Chrysanthemums are to be added next year to the list of flowers for which the so-called prospective prizes are established by the Massachusetts Horticultural Society. These prizes are offered for the best seedling raised by the exhibitor and shown for three years consecutively. Many seedling plants, notably Chrysanthemums, produce good flowers at their first blooming, and then deteriorate, and eventually prove worthless. Under the plan adopted by this Society the raisers only of well tried varieties are rewarded.

There were 136 seedling Chrysanthemums shown at the Philadelphia exhibition, and, according to John Thorpe, who acted as one of the judges, one out of every five had genuine and distinct merit. It may be added that Mr. Thorpe speaks with disrespect of that "scale of points" which had been devised to secure an accurate estimation of the quality of Chrysanthemums. He says that the judges made only one mistake, and that was in a case where they attempted to cipher out the value of a Chrysanthemum by a sum in arithmetic. After that the "scale of points" was discarded.

A correspondent of the *American Architect and Building News*, while confessing that no definite solution of the building problems involved in the "World's Fair" at Chicago has yet been arrived at, says that, "according to the best authorities, the Committee now expects to report with suggestions for buildings substantially as follows," as regards those in which our readers are most interested: "Agriculture, 1,200 feet long by 400 feet wide, with annex for power-house"; and "Viticulture, Horticulture and Floriculture, to be built in the form of a cross, each of the four wings being 200 by 150 feet, and the central rotunda 200 feet in diameter. An annex for heating boilers is also suggested for this building."

The *Popular Science Monthly*, quoting from a lecture on museums by Dr. G. Brown Goode, says that the earliest general collection shown to an American public was formed by a man named Arnold, at Norwalk, Connecticut, prior to the Revolution, and consisted of birds and insects. It first awakened an interest in scientific matters in President John Adams, who visited it several times "as he traveled from Boston to Philadelphia, and his interest culminated in the foundation of the American Academy of Arts and Sciences." But, it is added, the history of American scientific museums had its true beginning with the establishment of the Academy of Natural Sciences in Philadelphia in 1812 and the New York Lyceum of Natural History.

The *Builder* recently described a little church at Greensted, in Essex, England, which, although built of wood, has stood

for a thousand years, and is still in constant use. Its chancel is of brick, and seems to have been added in the sixteenth century; but the nave, which is thought to have originally been the whole of the building, and to date from the latter part of the ninth century, has only a plinth of brick, upon which rests a sill supporting the walls, which are formed of planks so thick as to be almost logs, about four and a half feet long and two or three feet wide. These walls are windowless, light entering only through dormers in the roof, which is of shingles and is not more than forty years old.

Mr. Maries, the well known collector, gives in the *London Garden* the following account of how *Primula obconica* was introduced: "When I was traveling in central China I was much puzzled how to bring out living plants 1,100 miles to the coast at Shanghai. I, of course, took plants of the things I thought were the best for garden purposes, but Ferns and herbaceous plants were altogether out of the question. I thought, however, that many seeds would germinate if they were kept in soil, so I collected surface soil from about Ferns and Primulas and other plants. This was kept in an old wine box, and eventually taken to Hong-Kong. I took this home twelve months afterward, and the soil was 'sown' in a glass house. The first thing that came up was *Primula obconica* in large quantities, several shrubs and a lot of Ferns. I have often seen remarks in *The Garden* about the native habitat of *Primula Sinensis*. This grows wild in all the gorges leading to the Yang-tse River above Ichang. Where I stayed, there in a cave temple, a few miles above Ichang, the clefts in the rocks above and below the cave entrance were full of *P. Sinensis* in immense tufts in full flower. This was in February."

Some systematic experimental work has been carried on at the Botanic Gardens of Georgetown, Demerara, since the seminal fertility of Sugar-cane has been proved. It has been established that propagation by seed in ordinary field cultivation will never be adopted, because in a great majority of varieties two years are required from the time the seed is sown before the seedlings mature, or fifteen to eighteen months are needed from the time they are strong enough to be planted out in the open ground. Besides this, the delicacy and slow growth of the cane in its infancy is an insuperable obstacle. The practical use that can be made of seedling cane is in obtaining new varieties. These seedlings vary very widely, and they have a marked tendency to improvement. In many cases the advance in quality and size of the cane has been remarkable. It is hoped by the Director of the Botanic Garden that the canes may be increased in size and weight and that the sugar content may be increased also. It is not improbable that in addition to these essential qualities the cane may be improved in habit of growth, resistance to drought, degree of earliness, percentage of fibre, etc., so that it is not impossible that a marked advance in sugar culture will be made from these seedlings.

The variety of uses to which the bark of the Cork Oak is put in southern Europe, as indicated in a report of United States Consul F. H. Schenck, will surprise most American readers. "Although," he says, "what gives most value to cork are the bottle corks, still it has other applications, some of considerable importance, such as plates or slabs for use on boilers, room carpets, the making of rugs, life-preservers, cork-dust bricks, hats, album-covers, picture-frames, jewel-boxes, bracelets and other objects of adornment; soles for shoes and boots, wheels of small dimensions for railroad cars, and the grease-boxes of the wagons; and recently it is applied as 'Corcho laminado,' or ornamental slabs, the invention of Don Buena-ventura Reull, of Barcelona, which is employed to cover plane surfaces and curves, employing them as carpets and for other uses. They make, moreover, huts for those who work at cork, and in Turkey they make cork coffins. In Italy they make images and crosses, shoes, horse-saddles, horse-shoes, arms, blacking, fortifications, furniture, soles for shoes, wadding for mortars, and obtain lampblack for printing in the United States, and the round or hollow cork is especially employed in the province of Valencia to husk rice. It is also used for bee-hives, pans and pails to deposit or carry milk; in ornaments in gardens, for relief maps to form the elevations, for floats in fishing apparatus, for pails where they cool water with ice or snow, etc. From the imperfect combustion of cork is obtained Spanish black, a product much esteemed for making printers' ink." To this we may add that artists in Italy and Spain carve pictures in relief in cork which have much the appearance of being moulded of terra-cotta; and that the packers of fruit for export now seem to prefer a coarsely granulated cork to the traditional sawdust packing.

It is not our purpose to criticise the conclusions reached by Mr. Greene. He has had better opportunities than any of his predecessors to observe these plants growing over wide ranges of country, and therefore under dissimilar conditions with regard to soil, climate and exposure, and whether his ideas of the specific rank of some of the western Oaks are generally accepted or not, the value of his investigation cannot be denied. A complete knowledge of these trees, or even an approximately complete knowledge of them, such as exists with regard to our eastern Oaks, the result of two centuries of investigation, will only be reached by the study of the trees in the field by a large

number of students approaching the subject from different points of view. The accumulated knowledge thus gained will give the best idea that can be obtained of this group of trees and of the limitation of the species. Botanists, however, will always differ in their conception of species, and in the case of the California Oaks the varieties of one will be species for another, or what one author considers a species another will regard as only a variety or as a natural hybrid. Information of this character, unsatisfactory, doubtless, as it may appear to those persons who believe that it is the duty of the naturalist to find unalterable characters for every species, will only be reached through field observations, and the more people who study our trees in the field, as Professor Greene is studying them in California, the more accurate and satisfactory will be our knowledge of them.

These two papers upon our western Oaks must be ranked among the important contributions which have been made toward an understanding of North American trees.*

RATHER more than a year ago we gave some account of the forest of the city of Lynn, an area of wooded land once held in common by the proprietors of the city for the fuel and timber they needed, and now restored to the use of the public. It is altogether the largest area which has been dedicated to park purposes in New England. The territory remains in nearly its original state, being a region of rocky hills with bold ledges and deep glens, through which rapid brooks find their way. From an article in the *Boston Herald* it appears that the commissioners who have been charged with the administration of this work have acted with wisdom, making several miles of substantial roads and laying convenient footpaths to the places of the greatest interest. The most important change has been in the completion of a new water-basin known as Glen Lewis and Walden Ponds. A substantial stone dam divides the basin into two sections, the upper level of which goes by the former name and the lower by the latter. The two form a long body of water of varying width, with branches extending between the hills, whose slopes are covered with healthy young Oaks and masses of White Pine and Hemlock. Looking up and down the valley from certain points this basin has the effect of a large river, and glimpses of it obtained from the neighboring hills are remarkably beautiful, while from some of the more elevated points prospects of great extent and varied interest stretch away on every hand. Of course it will be the aim of the management to preserve as far as possible the original features and natural charm of the whole region. It can be maintained more cheaply on these lines, and it will be much more satisfactory than if an attempt were made to subdue its wildness into pastoral or park-like scenery or to transform it into something artificial and formal. Some portions of it are to be held as a productive forest, and the success of this experiment will be watched with attention.

The important fact, however, is that the city of Lynn has led the way in establishing a public forest, and has thus set an example for other cities which have similar opportunities. It is true that there are few such regions of wild forest-land adjacent to bustling cities; but in several towns of the middle and New England states there are wooded gorges through which happy brooks are flowing, and tracts of broken land, and wherever these natural features exist it would seem the part of wisdom to take possession of them before they are obliterated by "improvements" of some sort. Some of the new cities which are growing so rapidly in the south will soon be lamenting over lost opportunities after the neighboring forests have quite disappeared. In the north-west, too, young cities are growing into an exact resemblance of older towns in the east without a thought of preserving the primeval forest which they are displacing, and yet a thousand acres of

Douglas Fir and Giant Thuya would make a forest-park so characteristic and so noble that, fifty years hence, it would command the admiration of the world.

The California White Oak.

THE largest of the California Oaks, one of the largest of the genus and the most graceful of all the species which inhabit North America, is the White Oak of the California valleys (*Quercus lobata*), of which a portrait appears on page 611.

The California White Oak attains sometimes a height of one hundred feet, with an enormous trunk seven or eight feet through, separating often near the ground into several main branches, whose ultimate divisions are long, slender and pendulous, the whole forming a broad head of surprising grace and beauty. The aspect of the tree seen from a little distance is rather that of the best type of the New England Elm than of an Oak, and more than any other tree this White Oak gave the peculiar park-like appearance to the valleys of central California, which so delighted travelers before these valleys were turned into Wheat fields.

The great size and the graceful habit of *Quercus lobata* are not the only beauties of this tree. The leaves which clothe the slender branches are large, bright colored and deeply lobed. The acorns, which are quite unlike those of any of our eastern Oaks, are slender, usually pointed, and sometimes two and a half inches long, with hemispherical tuberculated cups.

The wood of this tree is brittle, like that of all the California Oaks, and is practically worthless except for fuel. Economists deplore the poor quality of the timber produced by the California Oaks. There is, however, another side to this question, and California is, on the whole, a gainer in several thousand noble trees, which, had they produced timber as valuable as that of eastern White Oaks, would long ago have been converted into wine casks, and the California valleys would have lost forever their greatest charm.

We are not aware whether the attempt has ever been made in California to cultivate *Quercus lobata* as an ornamental tree. Outside of the state none of the California Oaks have ever succeeded in any marked degree, although various attempts have been made in different parts of Europe to grow them. They need, probably, the long, hot, dry summers which European climates do not afford. They might, however, be expected to succeed in Australia or in northern Africa, and should this prove true there could be no more splendid tree for the ornamental plantations of these countries than this Oak.

Our illustration is made from a photograph, communicated to us by Mr. William Alvord, of San Francisco, of a very fine specimen growing on General John Bidwell's farm in Butte County, one of the wonders of California's agricultural prosperity. This particular tree is remarkable for its great spread of branches, which have a diameter of nearly one hundred and fifty feet, rather than for the size of the trunk, which is only six and a half feet in diameter. The tree is growing on sandy, alluvial soil, and is honored with the name of "Sir Joseph Hooker," who visited and admired it in 1877 in company with Asa Gray.*

The Autumn Flora of the Lake Michigan Pine Barrens.—II.

THE most attractive flowers at this season, however, are the Blue Gentians, seen by thousands throughout the moist grounds of the barrens. Two species of them are recognized in our descriptive botanies, *Gentiana crinita* and *G. serrata*, but they run into each other so imperceptibly and completely that it matters little to which of the two many of the plants are assigned. Those whose leaves are broad and short are apt to have a more deeply fringed corolla, with some other distinctive marks, while those with narrow or linear leaves have the fringe of the corolla short or obsolete. Such will confidently be referred to the types of the respective species, but many that come between will be accepted with hesitation. The floral colors vary from pale to bright blue, the darker shades preponderating particularly with the narrow-leaved plants. When they grow in company with *Solidago Ohioensis* they either share the ground with it or more often form a kind of border to the yellow patches, apparently not succeeding in quite as moist localities as this Golden-rod may select. In similar places, but much less common, *G. Saponaria* and *G.*

* "Illustrations of West American Oaks," from Drawings by the late Albert Kellogg, M.D., the text by Edward L. Greene. Published from funds provided by James M. McDonald, Esq. Part I. San Francisco, 1889.—Part II. 1890.

*A portrait of this tree, made, perhaps, from the same negative, although greatly reduced, was published by Dr. C. C. Parry in an article descriptive of Rancho Chico, which first appeared in the *Overland Monthly* for June, 1888, and was afterward issued separately.

Andrewsii may be found, their corollas bright blue and scarcely opening. Very rarely *G. alba* will be seen, its flowers yellowish white. The last begins to bloom in midsummer and continues till the middle of September, being considerably earlier than any other Gentian here. On the higher ground *G. puberula* is not uncommon, its corolla very dark blue. It is a low plant, not often more than ten or twelve inches high, but succeeding admirably in the sand, and striking its long roots, generally two in number when they start from the base of the stem, deep down into the ground to the distance of two feet or more.

Vying with the *Solidagos* in contributing yellow flowers the present season (1890) was the shrubby *Potentilla* (*P. fruticosa*). They were as fully in blossom as in the earlier part of the summer. Though they continue in flower a part of September, their profusion this year was somewhat exceptional, and is doubtless due to a prolonged drought followed by rain the latter part of August, which has stimulated some plants into new activity and made these a conspicuous feature of the flora. Long strips of yellow bordered the wetter ground beside the sloughs, which run quite straight and parallel, sometimes for several miles. They usually grow in situations too wet for Golden-rods; but some that root in mossy bogs, like *S. neglecta* and *S. uliginosa*, are present to increase the effect, lifting above the shrubs their dense panicles of yellow.

A pretty plant of low stature, but looking frankly up at the beholder like a broad, white eye, is our only *Parnassia* (*P. Caroliniana*). It is very smooth, with a few wide or roundish leaves near the ground, and a smaller sessile leaf midway up its simple, scape-like stem, which bears a single flower at its top. This is peculiar, and always a subject of interest by reason of its crown of abortive filaments mixed with those which are anther-bearing. They are seen abundantly in the damp soil where the grass is not too rank, and often in such close proximity as to nearly cover the ground with white.

Two Orchidaceous plants still linger beyond others of their family, one in its proper season (*Spiranthes ceruna*), the other (*S. gracilis*) past its best. The former grows on bogs or in wet, grassy land, often hidden away beneath the small shrubs. No bouquet of wild flowers gathered where it is found would be deemed complete without a liberal supply of its chaste white flowers to give to the whole a delicious perfume. On account of its odor it has doubtless obtained a common name, especially among children, as the "Wild Tuberose." *S. gracilis* is seen in drier ground amid the overshadowing Pines. In similar localities, with these and with *Parnassia*, may still be found fair specimens of *Sabbatia angularis*. It has also passed its prime, but is common during the early part of September. It bears an ample number of flowers of a deep rose color, with a greenish star, bordered by a dark red or purple line, at the base of the spreading corolla, making them an unfailing source of attraction in its native wilds as one of our handsomest flowers.

Two species of *Coreopsis* are now in full bloom, *C. trichosperma* and *C. tripteris*, one or the other found nearly everywhere along the margins of the ponds or in very wet ground, the former the more common. When from six to twelve inches high it bears a flower barely more than half an inch across; but when it reaches a height of four or five feet it branches widely, and is well supplied with large heads that measure two inches from end to end of rays. With us it is a smooth plant, with a stoutish stem furnished with few leaves divided into narrow, almost thread-like segments. With its many flowers having golden yellow rays and a yellow disc, it takes a prominent place in the autumnal flora. *C. tripteris* has a greener stem and leaves of a different pattern. They are quite uniformly divided into three lanceolate segments, and are rather widely spaced on the tall, smooth stems. Its rays are not of so deep a yellow as in the case of *C. trichosperma*, but contrast sharply with the flowers of the disc, dark brown or almost black when they reach maturity, giving to the blossoms a different look.

Where the *Coreopsis* grows, and in localities not quite so wet, our prettiest *Gerardia* (*G. purpurea*) is found. Its average height is about a foot, and the open, nearly bell-shaped, rose-purple flowers are large for a small plant, being almost an inch in length, and often nearly as broad as long. The whole plant, though widely branching, is very slender, so that it looks as if its flowers would weigh it down, several of them appearing at the same time. It is exceedingly abundant and occurs throughout the region. The smaller flowered *G. tenuifolia* grows in like situations, but is not so common. Still another small flowered species is not out of bloom in the early fall, but much less common, or even rare. This is *G. Skinneriana*, the smallest of the species here. It has a few short and

thread-like leaves, which are far apart on a slender and mostly simple stem hardly a foot high. It likes the moist ground, but also takes to drier places than the other two. Both of these have paler flowers than those of *G. purpurea*, and are very pretty species. In the dry ground may be gathered the large, yellow flowers of *G. pedicularia*. Its foliage is handsome, the leaves being much cut up, and, together with the branching stem and flowers, are thickly covered with a viscid pubescence. The whole plant, except the flowers, frequently takes a purple hue. Were it not for the parasitic habit of the roots of *Gerardia*, making them difficult to cultivate, they should become most welcome flowers for the garden.

Four kinds of *Utricularia* may be met with in September. *U. cornuta* is abundant in the wet sand, often rendering the ground yellow with its numerous flowers. The stems are short, from four to ten inches high, each bearing three or four large yellow flowers. They grow in great numbers among the scattered Rushes or in spots bare of other plants in open, sunny places. They delight most in situations where the water has dried away, in the wet sand or mud, and would make a pretty border for the sandy margin of an artificial lake. The minute *U. gibba* is occasionally seen in the shallow water by the edges of the sloughs, its scape bearing one or two small yellow flowers. Still rarer is *U. resupinata*, its one small purple flower seeming to rest crosswise on the end of a scape two to six inches high. It affects about the same condition of growth as *U. cornuta*. *U. purpurea* is a purple flowered species also, but it floats on the surface of the ponds. The stems are long and branching, and covered with little bladders which serve to float it on the water. From these stems a few two or three flowered scapes rise above the water, with blossoms nearly as large as those of *U. cornuta*.

In many places in the driest sands *Monarda punctata* abounds, seemingly regardless of all conditions of moisture as dependent on the weather. Its large yellowish or purplish bracts are its most prominent feature, but, hidden among them or peeping out from their midst, are some dainty flowers—yellow, dotted with purple spots.

Artemisia Canadensis flourishes everywhere in the dry sand. Its flowers are inconspicuous if considered separately, but are very numerous on the wand-like stem and branches. But its finely dissected leaves and strict branching stem thickly covered with them make it, on the whole, a comely plant. It is sometimes hoary with a gray pubescence, but not so much so as some other species, being generally of a lively green, keeping its color well against the frosts when most of the other plants are dead.

Englewood, Chicago.

E. J. Hill.

Private Grounds and Enclosures in Cities and Towns.—II.

THE requirements of city dwellings in the way of out-door space, such as might be afforded by giving enlightened attention to the subject, are quite different from those of the suburbs. It is probable that the model city of the future will have an open, garden-like character radically in contrast with the closely built cities of to-day, and there are already indications that our cities will gradually be rebuilt in conformity with that idea. Every one who visits certain portions of Spain, or of Spanish America, is charmed with the feature known as the "Patio," the interior court of a dwelling-house, surrounded with arched corridors, a plashing fountain in the centre, perhaps planted with Orange-trees and Oleanders, and with the corridors bordered by rows of brilliant flowering plants in graceful pots or vases, while the air is musical with the song of numerous birds in their cages. This, like the "close," is an out-door apartment.

In most of our northern cities the climatic conditions are such that this inner court feature is impracticable. Yet a modification of it is something that should become a feature as characteristic as the patio is to the houses of Mexico or Andalusia. That is, instead of having the interior court a feature of a single house, let it be common to a neighborhood of houses. Let the space now devoted to unsightly back-yards and alley-ways in the quadrangle formed by the four streets of the usual city block be converted into an enclosed garden space, where children may romp in safety, free from the influences and dangers of the street, and where the open air may be enjoyed in common by all the surrounding households. It is possible to make a delightful garden of such a place.

Successful efforts have already been made in this direction. In one of the new districts of Boston a few years ago, in the building of blocks of houses on the four streets forming a

quadrangle, a turfed enclosure and playground was laid out in the centre, and it has proved a very satisfactory and attractive feature. This idea lends itself admirably to the construction of apartment houses in a neighborhood. The chief hindrance to its general adoption lies in the indisposition of builders toward acting co-operatively, even where their common advantage is concerned. But as the benefits of the plan become evident this obstacle will probably be overcome, and we may look to see at no distant future the new additions to our cities and the newly planned cities of this country so arranged that their dwellings shall enclose common pleasure-grounds for each block ample in space and beautiful in design. The maintenance of these in attractive shape would be as much a matter of pride with the residents as the proper care of their grounds is with the residents of an enlightened suburban or rural neighborhood.

The desirability of this plan in its application to a neighborhood of working-people is illustrated in an interesting experiment just tried by the city of Liverpool in the erection of houses for that purpose. An unsightly tract, covered with wretched hovels, was condemned by the city under the act of Parliament authorizing municipalities to take such action, turning out 1,300 people. Under special plans by Mr. Clement Dunscombe, who was afterward awarded a gold medal at the International Health Exhibition for this work, a quadrangle of pleasant five-story buildings was established with room for 600 or 700 people. The open space is devoted to a playground and garden, with five arched passage-ways from the streets. The garden is adorned with a fountain, and there are walks and roads of gravel. Should this plan be generally adopted by cities there would be no necessity of incurring large expenditures for demolishing buildings in tenement neighborhoods to create small parks; the needed breathing places would be supplied by these enclosures, and the whole work would be a profitable transaction for the city, for the Liverpool enterprise yields the municipal treasury a return of four per cent. on the investment, with the rates for rents placed at a remarkably low figure.

Another enterprise in Boston, or rather in the adjacent town of Brookline, is worthy of mention as indicating the tendency to an open character in city construction. Out on the beautiful new Beacon Street improvement, near Chestnut Hill, where the suburban neighborhood is rapidly assuming an urban character, expensive blocks of houses have been built on the "terrace" plan, after an artistic design. These houses not only have small individual gardens, but they face a large and handsome garden, the use of which is free to the tenants or purchasers for tennis, croquet and general recreation. The residents in these houses are also furnished daily, at reduced rates, with fresh vegetables and pure milk from a farm belonging to their builder.

Eventually our cities can perhaps be rid entirely of the drawbacks of their closely built character, which, with the attendant confusion, noise and confinement, is responsible for much of the disease and discomfort of urban populations. They will then be transformed into expanses of house-enclosed garden-spaces, which, with the establishment of large and numerous public parks, will combine upon the same area the main advantages of both city and country life.

Boston.

Sylvester Baxter.

Plant Notes.

Vanda Batemanni and Vanda Lindeni in Their Native Country.

THE thirty-five or forty species of the splendid genus *Vanda* are widely scattered in tropical Asia from the Malay Archipelago to the base of the Himalaya Mountains, where only *Dendrobiums* and some of the genera peculiar to a more temperate climate occur. These favored regions of southern Asia are especially noteworthy on account of the abundance and splendor of the Orchids which they contain.

The numerous groups of islands which compose the Malay Archipelago offer a vast field to botanical explorers. Unfortunately, many of the islands are surrounded by coral reefs which make landing difficult. At the time I visited this Archipelago I tried to navigate as near as possible to the coral reefs, endeavoring to explore the flora of each island with the aid of my field-glass, especially when the island was so small as to make the landing undesirable, the landing on these islands, as I have said, being always exceedingly difficult.

It was in this way that I first saw *Vanda Batemanni*, growing almost at the sea-level, when the tide was in, upon rocks rising from the water. In the little island where I found this

plant for the first time it existed in great quantities and in handsome straight specimens. The best were those which grew against shrubs or on isolated rocks. I saw several which were more than six feet high bearing on each side of their stems from four to eight floral spikes. I noticed many other Orchids on this island. The plants, with one exception, however, were not in flower, and I could not determine the genus at the time. The exception, however, made a great impression on me. It proved to be *Bulbophyllum grandiflorum*. The plant covered entirely a little tree with its flowers, producing at a little distance a most remarkable effect.

Vanda Lindeni, which I discovered in one of the islands of this region, grows in an entirely different way. It is found almost always on the dead branches of large trees, on the borders of small forests, or on fallen trees near the banks of rivers or brooks, but always at a certain distance from the ground. This remarkable species appears in clusters, with from fifty to two hundred stems, and sometimes with even more. It is a difficult matter to collect the plants, as the red ants, one of the scourges of that beautiful country, always make use of them to establish their nests in. The natives are very much afraid of their bite, which produces an eruption which lasts for several days. They are, therefore, exceedingly unwilling to climb the trees where the plants are growing for the purpose of collecting them. So I was obliged to employ another method for gathering the plants. I fastened several bamboos end to end and fixed a hook at the end of the long pole thus obtained. In this way I was able to pull down a few small clusters. As soon as the plants fell we dragged them at once to the water and gave them a good bath in order to rid them of the terrible guests with which they were often covered.

Vanda Lindeni is extremely prolific. I have seen clusters of stems upon which there were more than a thousand flower-spikes, most of them with from twenty to twenty-five flowers. Unfortunately, the specimens of this marvelous Orchid which I was able to bring living to Europe only give a very incomplete idea of what this plant is in its native home, both as to the size of the specimens and the abundance of the flowers.—Auguste Linden in *Le Journal des Orchidées*.

New or Little Known Plants.

Streptocarpus Dunnii.*

THIS is one of the most remarkable of the many remarkable plants of Africa. It was introduced to Kew in 1884 by means of seeds sent from the Transvaal, on the mountains of which, near a place called Spitzkop, it is said to be abundant. The seeds soon germinated, and the development of the plants was watched with increasing interest as the solitary leaf, of which each consisted, gradually assumed extraordinary proportions. Its ultimate size was over three feet in length by sixteen inches in breadth, the petiole as thick as, and no longer than, a man's thumb, whilst the blade extended along the ground like a large Rhubarb leaf. The principal nerves were very thick and fleshy, and the under side was thickly clothed with a reddish tomentum, the upper surface being also hairy, and gray-green in color. The effect produced by about a hundred plants of this *Streptocarpus*, which formed a border round a large bed of succulent plants in one of the large houses at Kew, was particularly striking. When, however, the plants flowered, their interest and attractions were considerably increased. From the base of each leaf, and extending some few inches up the midrib, there was a row of scapes packed close together and rising erect to the height of a foot or more, branched, and bearing a perfect sheaf of flowers (see Fig. 81, p. 609). One of the strongest of the plants had over one hundred flowers expanded at the same time. Before the flowering season was over each scape produced about sixty flowers, each of which was one and a half inches long, tubular, slightly curved, lobed, puberulous and colored a bright terra-cotta red. The plants commenced to flower in May and continued till August, when they ripened abundance of seeds.

A dry atmosphere, absence of shade, with a moderate amount of moisture at the root, and a well drained loamy

*Hooker in *Bot. Mag.*, t. 6903.

soil, were the conditions under which this plant grew so well at Kew. In pots the leaves are apt to get damaged, or to turn yellow toward the apex. Every year since its introduction this *Streptocarpus* has been a prominent feature in the Succulent House at Kew. So far as experience here has gone it is not worth while trying to save the plants after they have flowered. By sowing seeds every year a succession of young plants is easily maintained.

probably the finest *Streptocarpus* we have, is that called *S. Watsoni*. It has several large green leaves about twice the size of *S. Rexii*, and many flowered scapes of Pentstemon-like flowers, which are colored a rich rosy crimson with darker mottled lines in the throat. This hybrid has so far proved sterile with its own pollen, although it produces seeds when the pollen of some other kind is used. It can only be perpetuated by means of leaf-cuttings or by

Fig. 81.—*Streptocarpus Dunnii*, half natural size.—See page 608.

By crossing *S. Dunnii* with several other species some interesting and pretty-flowered hybrids have been obtained at Kew. The first were named *S. Kewensis* (from *S. Dunnii* and *S. Rexii*) and *S. Watsoni* (from *S. Dunnii* and *S. lutea*). These were figured and described in the *Gardeners' Chronicle* in 1887. Other crosses from these and *S. Saundersii* have since been raised, while by crossing the hybrids with each other and their parents a large number of forms, showing considerable range of variety in color and habit, have been the result. The showiest of all, and

crossing its parents. By this latter method a good supply of seeds may easily be had, and the plants from them show scarcely any difference from that first flowered, except, perhaps, slightly in the shade of color. Many of the latest crosses which have flowered this year at Kew are of considerable promise. By crossing and selecting from the best of these plants it is probable that in a few years we shall obtain a race of *Streptocarpi* which, in a greenhouse, will fill as large a place as the *Gloxinia* now does in the stove.

Kew.

Foreign Correspondence.

London Letter.

GAMBIER.—This is an article of considerable value to the tanner, the dyer and the druggist. It is obtained from the leaves of a Rubiaceae shrub known as *Uncaria Gambier*, and is an ally of the Negro Peach (*Sarcocephalus*) and the Cinchona. Hitherto its cultivation and preparation have been a monopoly of the Straits Settlements; but owing to the fact that it has become difficult to procure, and, when procured, so often proves almost worthless through bad preparation and adulteration, its extended cultivation has for some time occupied the attention of the authorities at Kew. Seeds of the plant were therefore obtained from Singapore and a batch of plants raised from them at Kew. These have lately been dispatched, under the personal care of Mr. Morris, to some of the English colonies in the West Indies, where it is anticipated they will thrive and prove to be the starting point of a valuable industry. In the *Kew Bulletin* for October, 1889, attention was directed to the value of Gambier as "an article which every tanner in the kingdom uses more or less, and no other can take its place. It used to cost £10 per ton and now costs £45."

Gambier is obtained by boiling the leaves of the *Uncaria*. It is imported in the form of small squares or little round cakes. The finer samples are used in India for chewing along with betel leaf and medicinally. The plants grow rapidly and yield several crops of leaves every year for from fifteen to thirty years from the time of planting in the fields. They require a moist tropical climate, such as is favorable to the cultivation of the Cocoa-plant, Vanilla, Ginger, etc. The Gambier industry is at present chiefly in the hands of Chinamen, but their system is said to be wasteful and the preparation of the article unsatisfactory. With improved methods of cultivation and preparation the value of Gambier may be considerably enhanced. Its introduction into the West Indies will probably prove as important an event almost as the introduction of the Cinchona from Peru into India. In addition to its value to the tanner and the dyer, Gambier is known to possess useful medicinal properties; it is also used in beer-brewing. I call attention to this plant and its introduction into the West Indies because I observe that the United States Consul at Singapore has reported that "the exports of Gambier to the United States during the last three years have amounted to \$1,060,000."

LILY-FLOWERS AS FOOD.—It is well known that the dried flowers of certain species of *Lilium* form an important article of food with the Chinese and Japanese. Examples of the Lily-cakes as prepared in Japan and China are in the Kew Museum. These cakes are used to flavor soups and as a vegetable, besides being supposed to have tonic properties. In the Consular Report on the trade of Chinkiang for the year 1886 it is stated that "The export of Lily-flowers has increased this year to 7,677,622 pounds. Not more than one-fifth is consumed here; the rest goes south, where it is used to flavor soup." In the *American Naturalist*, vol. xvi., p. 119, it is stated by Professor Penhallow that the bulbs of various species of *Lilium* are utilized as a source of food by the Japanese. In the Kew Museum there are examples of the food obtained from the bulbs of *L. cordifolium* in Japan.

I know of only two other recorded instances of the use of flowers as food. Of course by flowers the petals only are meant. The heads of the Cauliflower and the Artichoke are excellent articles of food, in which, however, the true flowers play a very small part. In India the flowers of the "Mahwa-tree" (*Bassia latifolia*) and of the "Phog" (*Caligonum polygonoides*) are collected and eaten by the natives. The "Phog" is made into bread, and Professor Church, who analyzed a sample of it, said that it contained more nutrient properties than rice and almost equaled Chick-pea. Mahwa forms an important article of food in many parts of India.

AMERICAN VINES.—In a recent letter I referred to the important place some of the species and varieties of American Vines now filled in those parts of Europe where the cultivation of the Grape is a staple industry. The destruction of this industry was threatened by the terrible Phylloxera, but by using the American Vines as stocks for the preferred varieties of *V. vinifera* this calamity has been averted. In time there will scarcely be a vineyard in Europe in which American Vines do not act as nurses to the best wine-producing kinds. The success of this experiment has induced other countries to follow suit, and I hear that for one of the Indian principalities 50,000 American Vines have lately been ordered from France. Has any one tried to cross *V. vinifera* with the best of the American kinds? Good results ought to be obtained in this way. Varieties possessing the constitutional peculiarity which

renders them indifferent to the Phylloxera and with fruits equal to the best of the varieties of *V. vinifera* would be of immense value.

NEW CHRYSANTHEMUMS.—The National Chrysanthemum Society this week awarded first-class certificates to the following:

Beauty of Castlehill (Japanese).—An English seedling. The florets are large, rich yellow, tinted with bronzy red. The general appearance of the flower suggests Boule d'Or.

Beauty of Castlewood (Japanese).—This is in the way of E. Molyneux and Mrs. C. Wheeler, the florets being large, broad, deep orange yellow on the one side, rich maroon on the other. The flowers are as good in form as those of E. Molyneux.

Danae (Japanese).—Large-flowered, the florets long, broad and twisted, and colored brilliant yellow, shaded with red.

Countess of Lytton.—Very near to Ralph Brocklebank, but distinctly primrose in color. It is a sport from Meg Merrilies.

A. C. Kingston (Japanese).—The flowers of this are large, compact and good in form, while in color they are rich crimson. This is likely to become popular as an exhibition variety.

Sunset (Japanese).—A large-flowered variety of fantastic form, the florets very broad and colored orange on the upper side, bright red on the lower, while the reverse is silvery.

Princess Waldemar (incurved).—A beautiful flower, medium in size, compact and regular, and colored a rich flesh pink. It is in the way of Eve.

Violet Rose (Japanese, incurved).—A handsome variety, the florets somewhat incurved, but not compactly so, and colored a bright rose-red. This is a distinct and promising sort.

Mrs. E. W. Clarke (Japanese, incurved).—A large-flowered variety, with the florets incurved somewhat regularly, and forming a rather high centre; the color is bright lilac or mauve. It is a first-rate addition to this section of Chrysanthemums.

A USEFUL INSECTICIDE.—All Orchid-growers know something of the ravages of thrips and the difficulty of keeping them under in Orchid-houses. Some plants, such as the green-leaved *Phalænopsis*, *Phajus tuberosus* and *P. Humboldtii*, *Miltonia vexillaria* and *M. Roezlii*, are only rarely seen without the accompaniment of thrips or their marks. Sponging, tobacco fumigation, tobacco solutions, snuff and other supposed remedies are not always to be relied upon; at any rate, such is my experience. I am pleased, therefore, to be able to recommend what has proved perfectly successful as an insecticide for Orchids—namely, an article sold here under the name of "Lethorion." It is in the form of a cone, which, when set on fire, burns slowly and produces a peculiar vapor which does not injure the most delicate Orchids, but effectually destroys insects. We have used it for *Oncidium*s, *Odontoglossum*s and *Masdevallia*s, and I know that it has been used for *Phalænopsis*, *Cypripedium*s and Orchids generally, and has proved effectual in every case. It is easily applied, and the only objection to it is the peculiar and somewhat disagreeable odor that remains in the house a day or so after its use. In this respect, however, it is no worse than tobacco. I have seen so many collections of Orchids suffering from the attacks of thrips, etc., as well as considerable injury done by attempts to eradicate the insects, that I gladly make known the value of "Lethorion" as proved by myself and others. I know nothing of the vender nor of the composition of "Lethorion," but I believe it can be had from most dealers in horticultural sundries.

Rose Notes.

THE short days of the year make an interesting period for the Rose-grower, because continual watchfulness is essential at so critical a time. Ventilation should be given whenever the weather will permit, for pure air is essential, and yet the oft-repeated warning against draughts should never be forgotten, for nothing is more injurious to the soft young growth of a Rose than a current of cold air. The plants should now be syringed early in the day, so that they may dry off again before night, otherwise they are liable to be chilled, and any check is felt at this season.

It is not prudent to keep the house at the same temperature during severe and more moderate weather; the extra fire-heat demanded to produce such a temperature in extreme cold seems to reduce the vitality of the plants, and it is therefore the usual practice among careful growers to permit the temperature of the Rose-houses to fall from three to five degrees lower on cold nights.

While on this subject of temperature it may be stated that all varieties do not flourish at the same degree of heat, and

for this reason it is best where the space devoted to Rose-growing is limited to limit likewise the number of varieties grown, for it is certainly better to grow two varieties well than to attempt to grow a dozen sorts in one small house and then fail with eleven of them. For example, Papa Gontier and American Beauty are seldom seen equally healthy in the same house, for the reason that while the former enjoys a night temperature of fifty to fifty-two degrees the latter is seldom seen at its best unless grown at fifty-eight to sixty. W. F. Bennett also seems to enjoy a moderately high temperature, and strange as it may seem in the case of a Hybrid Tea, still it is true that some of the best plants of this variety have been grown quite wet at the root. This rule as to moisture, however, may not be infallible, as the behavior of this variety varies considerably in different soils.

Among the earliest hybrid Roses to be seen this season are fair blooms of Mrs. John Laing, some of these having been in the market for two or three weeks past. Apparently this fine variety has only been distanced in earliness by the new pink

so well in South Carolina that some of our northern nurserymen take this means of supplying their stock. That is, they consider an establishment in the south for raising such varieties preferable to importing them from Europe. This system possesses the additional advantage that the home-grown stock is all on its own roots, whereas the imported Roses are almost invariably budded or grafted.

The use of wood ashes as a fertilizer in Rose-houses is again strongly advocated by some growers, and, while these are undoubtedly of value, yet it will not do to depend on them entirely. Wood ashes will certainly not encourage the spread of Fungus through a bed as an over-application of barn-yard manure will, and in a comparative test of two parallel beds of the same variety, in one of which the fertilizer was ground bone and in the other wood ashes, the evidence at the time I saw them, about October 15th, was in favor of the ashes; but, of course, it was too early in the season to accept this evidence as final.

Holmesburg, Pa.

W. H. Taplin.

A California White Oak (*Quercus lobata*).—See page 606.

hybrid shown by Mr. Julius Roehrs at the late Chrysanthemum Show in Philadelphia and at some other exhibitions. This latest candidate for honors as a forcing variety has thus far been shown without a name, and consequently has been claimed by some Rose-wise persons to be merely an old variety re-introduced, while others are equally positive that it is really new. Be this as it may, the flowers shown were of good color, size and substance, and the introducer deserves credit for making its good qualities known whether it be new or old.

The new Polyantha Rose, Clothilde Soupert, to which some reference has already been made in these columns, has created a good impression during the past summer, its charming little flowers being so freely produced that it will doubtless be largely planted next season. These miniature Roses have become very popular of late years for bedding out, and with good reason, too, for they are seldom out of bloom.

Wootton as an out-door Rose in this locality did not prove a success, but for forcing it is again on trial to a considerable extent, and as its needs are better understood it will probably pay for the experiment. Possibly this variety may do better out-doors in a more southern latitude, as several of the Hybrid Teas that cannot be grown to advantage here are now grown

The Calochortus in Cultivation.

IN my experience here the various species of Calochortus are hardy out-of-door plants. But eastern growers who use them for forcing purposes may perhaps gain some hints as to their cultivation by some statement of the conditions which here secure the best growth. In England they are hardy, and I believe that Messrs. Gillett & Horsford, of Southwick, Massachusetts, treat them as half hardy. I am inclined to believe that many species would prove half hardy in the east. *C. Nuttallii*, usually known as *C. Gunnisoni*, the true *C. Gunnisoni*, *C. macrocarpus*, *C. aureus*, *C. lugens* and *C. flexuosus* are natives of the Great Basin, and are occasionally subject to as low a temperature as twenty degrees below zero. It is a dry cold, and the bulbs are in loose sand from four to six inches deep. I have dug *C. Leichtlinii* in the Sierra Nevada at an altitude of 9,000 feet and a few hundred yards from snow banks that did not melt that season.

A snow-fall of a few feet is common where *C. nudus*, *C. elegans* and the Oregon species grow. Here on the coast range of northern California fourteen degrees above zero is the severest temperature experienced, and in it the leaves of

Calochortus suffer no injury although frozen stiff every morning.

It is seldom that two species of Calochortus are found growing together. In a given section of country but one type of the Mariposa Tulip is usually found and one or two species of the Star Tulips; the Mariposa Tulips in warm, open situations, the Star Tulips in open woods or shaded hill-sides. Each species seems to cling to its particular soil and exposure, and even varieties of the same species seldom intermingle. The following usually are native to a sandy soil with a mixture of mould: *C. aureus*, *C. macrocarpus*, *C. Nuttallii*, *C. flexuosus*, *C. Gunnisoni*, *C. Kennedyi*, *C. venustus roseus*, *C. Weedii* and *C. Palmeri*, among the Mariposa Tulips, and *C. albus* of the Star Tulips. *C. luteus* is native to a stiff, rich, clayey soil, that peculiar clay known in California as adobe. *C. splendens* and the varieties of *C. venustus* known as *oculatus*, *citrinus* and *purpurascens* are found in light shallow clays. *C. Leichtlinii* is alone found in decomposed lava, sand and ashes. Of the Star Tulips, *C. lilacinus*, *C. nudus* and *C. uniflorus* grow in the sandy loam of moist meadows; *C. pulchellus*, *C. Maweanus*, *C. Bentharii*, *C. cæruleus* and *C. elegans* are usually found in the light soil, gravelly or clay, of open woods.

The species I have named comprise nearly all of the cultivated species. Nearly all of the species named will stand much moisture during the growing season. The uplands where many of the Mariposa Tulips grow are at a saturation point for some time during the rainy season, and of course water stands on the meadows where *C. lilacinus*, etc., grow during the winter. But before the Calochortus are ready to blossom the water has dried up and the soil begins to bake. A few weeks later the plant is dried up or blown away and the soil is baked hard. Nature has provided the bulb with a protection from the heat and dryness in the shape of a fibrous covering which is thickest in the desert varieties. It will be found that as often as not the rootlets at the base of the bulb are dried up when the plant is in bloom; in other words, the growth has ceased, and it only awaits the ripening process.

In planting them the bulbs should rest on firm soil. I use boxes about ten inches deep and fill up to about four inches of the top with clay loam and tramp it down. I then plant the bulbs, using a little sand or loose soil to stick them in. I fill up with the soil I consider best for that particular species and press firmly. Take it as a whole, a mixture of sandy loam, with a little mould or finely rotted chips, will more nearly accommodate all species than any other mixture that I have tried. Mariposa Tulips need a warm, sunny situation, Star Tulips partial shade; but very good results can be had in planting side by side regardless of this. Of all the species that I have grown I have found *C. lilacinus* the most susceptible to cultivation, and next to it the varieties of *C. venustus*, especially *roseus*. *C. venustus oculatus* is wonderful in its variations in coloring, *C. venustus citrinus* is only different from it in color, and there are shades innumerable between the creamy white of one and lemon-yellow of the other.

To choose the most desirable from a number of species, all of which have the beauty and coloring of the Calochorti, is a hard undertaking. If I were to choose four they would be *C. Nuttallii*, *C. venustus oculatus*, *C. albus* and *C. pulchellus*, with an inclination to ask that *C. lilacinus* be thrown in as an extra.

Carl Purdy.

Our Twenty "Best" Apples.

THE American Pomological Society's list of apples contains but twenty native sorts to the names of which are affixed the letter "b," indicating that, in the judgment of the Society, or of such of its membership as were present in the meetings where the quality of apples was under discussion, these alone are entitled to rank, as to dessert quality, above all other apples native to this continent. This list contains no sweet apples. As to season, four are summer, three early to late fall, and thirteen are winter varieties. In origin seven are from New York, three from Massachusetts, two from Connecticut, one from Pennsylvania, six eastern, with state unknown, and one probably from Ohio.

May it not be permissible and profitable to review this list with an eye to its amendment, and perhaps its increase, at some future meeting of our Society? May it not be true that in other states, from a wider range of country, there are apples deserving a place in this roll of honor? Perhaps a majority of the Society might favor dropping the names of a few which have ceased to be planted from cultural defects or because they are superseded by more desirable sorts. Mere high quality, or local preference, without other merit, ought not to admit to a

select fruit list endorsed by a continental society of practical fruit growers. The word "best" should not be made too narrow in its application here. The quality being the same, or equal, other merits ought, I think, to be taken into consideration. Beauty must not be entirely ignored. Adaptation to general or a wide range of cultivation is worth considering. Health and productiveness of tree are important considerations. Not that these should admit, but that the lack of them may exclude an apple which, considered merely on its flavor, would be a proper candidate. I think we may take Pomme Grise, for instance, as an apple of so few other merits that its excellent quality alone should not give it a place.

AMERICAN SUMMER PEARMAIN.—This fine apple, tracing its descent to an equally popular, but really inferior, English apple, is well entitled to its place. It has beauty, medium size and a fairly productive and healthy tree, requiring high culture, however, to develop the merits of the fruit.

BELMONT.—From all points here is a first-rate apple, of good size, great beauty, a healthy and productive tree, with a crisp, delicate and most agreeable fruit. Its season extends beyond the holidays.

BETHLEHEMITE.—Like the preceding, this apple is of unknown origin, and the excellence of both was first widely recognized in Ohio, this being named for an Ohio town, as Belmont is for an Ohio county. Downing thinks it plainly a seedling of Newtown Spitzenberg, which it much resembles. The tree is a good grower and productive, while the fruit, of medium size, is well formed and well colored. The flesh is juicy, rich, mild and aromatic. An all winter apple.

BULLOCK'S PIPPIN is the oldest American Golden Russet, also locally known as Sheep's-nose, a small, plain-looking apple, but of a most remarkable pear-like flavor. The flesh is yellow, tender, juicy, spicy and rich. Early winter. It does not always ripen up perfectly, and the tree is subject to disease. Perhaps this variety might be dropped from the "b" list, along with Pomme Grise, which seems to be a close relative.

COGSWELL.—Here is an old Connecticut fruit, and to it are assigned by the books almost every merit—a vigorous, productive tree, fruit of a size above medium, regular in form and size; a rich yellow color, well marked with red; fine grained yellow flesh, tender, rich, juicy, aromatic and a good keeper. Why is not such an apple more often found in the general market?

EARLY JOE.—A well known little August apple, which is often seen in market and deserves its place. Yellow, with red striping; flesh white, tender, juicy, vinous. A general favorite.

ESOPUS SPITZENBERG.—Downing says this Spitzenberg is considered by good judges equal to the Newtown Pippin; but our Society excludes the latter from a list where the former stands prominent. "Flesh rather firm," says Downing, and it is all of that. In fact, it is a hard apple that never softens until it decays, and its high flavor alone gives it a place here. It is really a "best" pie-apple. Unfortunately, the tree is not vigorous, and it is usually an unprofitable apple to grow for market.

FALL WINE.—This fruit is so subject to disease as to be not worth growing, except perhaps in a few localities, and I think it should be dropped, although a fine apple and the nearest to a sweet one that appears on this list.

GARDEN ROYAL.—Here is my favorite; and yet it must be said of it that it is strictly a garden apple, and worth growing only on the condition of high culture. It is of sea-side origin, and I have never seen it thriving so well as within the range of New England's fog-banks. The tree is healthy and productive, and with the high culture it requires I do not see why it may not be grown profitably from Portland, Maine, around to New York City. Wherever it can be well grown there is money in it. Season, August and September.

MELON.—A New York apple of good size, yellow, handsomely striped and shaded with red. Tree a moderate grower, and usually a good bearer. The fruit is of full medium size, often ribbed, but not prominently. Flesh white, tender, juicy, sub-acid, vinous. It bears handling poorly, but carefully packed it can be sent short distances in good order.

MOTHER.—Another apple of the Massachusetts coast which grows nowhere else so well. Smallish, conic, red. Flesh yellow, tender, rich, sub-acid. Rarely seen in market, yet common in private grounds and highly esteemed.

NORTHERN SPY.—It is difficult for me to understand why the Spy is taken and King of Tompkins left off this list. In quality the Spy varies greatly, and at its very best is better than the King; but not as usually seen in the market.

PORTER.—This is the favorite fall apple of Massachusetts and

when well grown its quality is certainly very good. It has, however, been to a great extent superseded by the Gravenstein, and growers call it an unprofitable apple in competition with that variety.

PRIMATE.—There is no better late fall and early autumn apple than the Primate, and it is easily grown.

RED CANADA.—It is hard to find fault with the old "None-such," and they still grow it large and fair in some parts of Michigan. But it is an apple very apt to "go back" on the planter. In New England and generally in the east it is a sad failure.

SPITZENBERG.—This (Newtown) Spitzenberg is much more to my taste than its brother of Esopus. The tree is more healthy and productive in the long run, and the fruit is not only rich, spicy and vinous, but it is tender and crisp.

SUMMER ROSE.—Here is a nice little apple, not much larger than the Lady Apple, and quite as good in its season, but no more worthy a place in a select list.

SWAAR.—A noble apple truly, as Downing calls it. No one will object to the Swaar; but few have the soil to grow it in perfection. It ought not, therefore, to be recommended for general cultivation.

WAGENER.—A good tree and a choice apple, provided the fruit is severely thinned. It is only so that it can be entitled to the place assigned it. As usually grown it is unprofitable and its high quality much obscured.

Let me conclude shortly with the query, Whether the time has not come to revise, prune and possibly somewhat to enlarge this list of America's "best" apples?

Newport, Vt.

T. H. Hoskins.

The Grape Market.

A CORRESPONDENT writes that "he does not understand why grapes should be so cheap when there is such a scarcity of other fruits." One reason for these low prices I attribute to over-production. This idea is often characterized as ridiculous, but that the supply exceeds the demand, except at the lowest prices, is evident to all observers. The area devoted to grape culture in New York State during the last decade has been immensely increased, and it is from this region that New York and the surrounding cities receive their chief supplies, and notwithstanding serious damage to the crop in some parts of the state from rot and mildew our markets have been flooded the past autumn with this fruit to an extent never before known.

Another agency in depressing prices is the immense quantity of unripe and inferior fruit sold. Purchasers become dissatisfied and disappointed after a few trials of such fruit, and many refuse grapes altogether on this account. Growers injure themselves and the market by putting out such fruit. The desire to be early in the market so as to command the highest prices often overreaches itself, unless the fruit is of excellent quality.

The growers are not always responsible for this inferior quality of their products, for it is a well known fact that soil and climate are important factors in this matter. New Jersey fruits as a rule are more highly colored and better flavored than the same kinds produced in western New York. The Concord, most widely disseminated of all our grapes, is of much higher quality grown here than there. It seems to improve, not only in this respect, as it comes farther south, but also loses its foxiness. This change holds good with other fruits, and is doubtless due to our longer season, and perhaps to the presence of more iron in our soil. I once took some Baldwin apples to a meeting of the western New York Horticultural Society which were so highly colored that some of the experts there questioned the correctness of their name.

This difference in the quality of fruits grown in different localities is apparent to persons of critical tastes who have given any attention to the matter. It is worth while to quote the results of six chemical analyses of Concord grapes made in 1885 by Professor G. C. Caldwell, of Cornell University: Three samples of New Jersey Concorde showed an average of 16.09 per cent. of sugar in the juice, and three of New York Concorde an average of 13.54 per cent. of sugar. The grapes found in our markets would doubtless show a much wider difference if submitted to the same test.

A few years ago, when the Niagara Grape Company began to solicit purchasers for their vines on the terms they had adopted, the plan met with a good deal of criticism. People who accepted those terms were laughed at for their folly in allowing strangers to get a mortgage on their lands in this way, and it was predicted that Niagara grapes would soon be as cheap as Concorde. The lapse of time has proved these prophecies true in part. Most of these so-called lunatics who bought

the vines early have realized a handsome profit from their venture. The past season, however, has developed the fulfillment of the prophecy as to the price, as Concorde and Niagaras have sold at the same price; and in fact these cheap Niagara grapes were not as good as good Concorde. The commission merchant who sold my Niagara grapes told me that it was hard to hold up the price when they could be bought on the same block at thirty cents for a five-pound basket. I bought one of these baskets which came from a vineyard in central New York. The clusters were of good size and compact, and the berries full and large, but a single taste was enough to show that for table grapes they were dear at thirty cents a wagon-load. It is little wonder that many Niagara grapes have been sold in this market for from fifteen to twenty cents a basket, although when expenses for commission, freight, expressage, packing and picking have been deducted the margin of profit for the grower must be very slender. It is grapes of this quality which depress the market and tend to ruin the reputation of any variety. Merchants do not regard quality as much as they should, and buyers generally try to force the best down to a level with the cheapest. It seems, therefore, that the only remedy for the present low prices is to increase the percentage of fruit of the first quality and reduce the production of inferior grades. When consumers find they are getting a fruit that is palatable and healthful they will buy abundantly. As it is they have reason to be suspicious of anything in the shape of a grape.

Montclair, N. J.

E. Williams.

Cattleya Percivaliana alba.—One of the few plants in existence of this rare and beautiful variety is now in full bloom in the collection of Mr. Hicks Arnold of this city, and it carries three handsome flowers well formed and of snowy whiteness except a rich orange stain in the throat. Each sepal is broad and flat, the petals round and furnished with a fine fringe. The lip also is broad and delicately frilled. The plant occupies a basket, and is suspended near the glass throughout the year. The ordinary form of *C. Percivaliana* is now enriching many collections with its showy blossoms, and is gaining popularity among florists as a useful and free-flowering species for cut flowers. It is very easy to cultivate, and in its native home is found growing at 4,000 to 5,000 feet elevation on rocks fully exposed to the sun. Three, four and sometimes five flowers make their appearance on a spike and remain a month in good condition. It will thrive well either in a pot or basket in a compost of good fibrous peat and a small portion of clean sphagnum with ample drainage. After the flowering period is past water should be sparingly given to ripen the new bulbs. During the summer months, the growing period of the plant, it should have a temperature of sixty-five degrees. A few degrees higher will prove beneficial, and a gradual reduction of water as the new growths approach completion will induce them to flower.

The Forest.

Value of Mountain Forests.

THE first and most important function of mountain forests is the preservation of the mountains themselves by clothing them with soil. The relation of mountain forests to the soil out of which they grow is curious and interesting. The soil now produces the trees, but the forest has produced the soil which now nourishes it. There was a time when there was no soil on the mountains of New Hampshire, nor on any portion of the Appalachian System—when the mountains were only ridges, slopes and summits of bare rock. They were composed wholly of mineral substances, of matter entirely inert and incapable of supplying food to vegetable organisms. There was not an atom of soil on the rocks of the whole region, and no vegetable growth of any kind. Then, when conditions permitted, Nature began a new order of things here with some of the lowest forms of vegetable life, resembling the lichens of our time. Some of these could grow here and there on the rocks, and whatever could grow would die and decay, but would not wholly perish. Some slight particles of its fibre or substance would remain undestroyed through all the changes of decomposition, and in the course of centuries or thousands of years a thin film of soil was accumulated here and there sufficient to nourish vegetation of a little higher character and organization than had belonged to the pioneer organisms.

How great the distance from that far beginning to the first trees! And very poor and inferior trees the earliest ones were, when they did appear, compared with those which make

our forests now; but they were the best that the still scanty soil would sustain. Ever since the leaves of the first trees began to fall the trees have been slowly adding to the deposit of soil which now covers the rocks, and which has reached the depth and productive potency required to sustain the noble forests of our own time.

The great stratum of fertile, life-producing soil which now lies folded around the shoulders of the hills is the result and accumulation of patient ages of dendral toil. Nature has wrought incessantly, through mighty cycles of time, to clothe the desert rocks with life and beauty, and in the untainted air of these lofty slopes and plateaus she now grows forests which are like the columned aisles of vast cathedrals. Ships which cleave the waves of every sea, and the cottages and palaces of mighty cities, with myriads of structures for man's varied industries, have been builded of the materials supplied by our mountain forests. The superior quality of the timber now grown, and the vast quantities in which it is produced, are effects of the wonderful fertility which the soil has attained. It is richer than ever before, but it has not reached the limit of possible productiveness. There is no such limit, indeed, and if our mountain forests were rightly managed they would forever increase in fertility, and the quality of their timber would be thereby gradually improved.

A forest is the only crop, so far as I know, which can be produced perpetually on the same ground without diminishing in any degree the fertility of the soil. It is a remarkable fact that a forest not only does not impoverish the soil out of which it grows, but that it actually enriches it. As the soil is thus improved it responds by producing superior timber. A mountain forest would yield better timber, and more of it, at the end of a thousand years of proper management than at the beginning, and proper management means and includes the cutting of every tree when it reaches its best estate.

FARMING IN MOUNTAIN REGIONS.

The entire effort at farming in mountain forest-regions in this country is often a most destructive and suicidal mistake. Much of the ground that has been cleared for cultivation in such regions is so steep that if forest-conditions are once destroyed upon it the soil is certain to be washed away. It has always been manifest to intelligent observers that such land is suited to the perpetual production of timber, and of that crop alone. In many instances in our state land has been cleared and "farmed" with very slight returns which would be much more valuable than it now is if it were still clothed with forest. The yield of farm products in such cases is scanty and uncertain. In some places the land is too high and cold for successful cultivation. There are frosts late in spring and early in autumn, and sometimes in every month of the brief summer, and the soil is soon exhausted. It would be difficult to find anywhere an instance of more obvious natural adaptation to a particular function than our whole mountain forest-region exhibits in its fitness for permanent forest-growth and its unfitness for any permanent beneficial use after forest-conditions have been fully destroyed. It would have been much better if some of our "abandoned farms" had never been cleared. In some parts of our country vast values have been permanently blotted out by clearing and cultivating mountain land, and those states will be poorer for all time to come by reason of the resulting destruction and removal of the soil of considerable areas of their mountain regions.

RUIN BY FIRE.

The most fatal agency in destroying the soil of a mountain forest-country, and in wrecking the mountains themselves, is that of fire, and in the history of most mountain forest-regions the operation of this agency has been closely connected with the attempts to cultivate the soil to which I have just referred. In various regions of the Appalachian mountain system many of the farms have been cleared simply by burning the timber and brush left on a tract after it has been lumbered over, and the first crop is planted in the ashes. In a few years the soil is exhausted or washed away, and the farmer goes a little farther up or down the valley, or across the stream which runs through it, and repeats the operation. But the injury to the mountains which is caused by the destruction of the soil of these limited tracts which have been cleared for cultivation is trivial when compared with the losses which have resulted from the forest-fires having their origin in these clearings.

When we consider the rapidly increasing density of the population of our country, and the great advance in the value of all fertile lands, especially in the eastern states, it is obvious that the complete destruction of the soil of any considerable area is a very serious matter. There are few kinds of losses or misfortunes affecting property which are so calamitous as

this. It is a crime against posterity, a permanent subtraction from the wealth and the capabilities of the country. The soil is, to a very great extent, the country itself. A burned city can be rebuilt, and the system of insurance distributes the loss widely. But there is no insurance on the soil of our mountain forests, and when it is once thoroughly burned it will require mighty cycles of time to restore it. Its producing capacity for ages, and all the "promise and potency" of a perpetual succession of valuable crops, are at once reduced to nothingness.—*From the Report of J. B. Harrison, Commissioner of Forests for New Hampshire.*

Correspondence.

A Good Tree for the South.

To the Editor of GARDEN AND FOREST:

Sir.—Your southern readers, perhaps, are not generally aware of the value of *Moringa pterygosperma* as an ornamental tree in the southern states. It is the Horseradish-tree of India, the fleshy roots when young being equal if not superior to the roots of the common Horseradish. Those in Mexico are highly prized and form a staple article of diet. From the seeds are prepared the finest "oil of benne" used by jewelers, and the seed-pods are said, when young and tender, to be edible cooked in soups.

The tree is a very rapid grower. I have specimens that are only four years old from seed and which are well bushed out and form excellent shade trees fully thirty-five feet in height with trunks from six to eight inches in diameter, while some of my young trees, planted only a year ago, are twenty feet high. The *Moringa* has graceful, ternately decomposed leaves, and produces, when only a year old or sometimes even earlier, clusters of delicate flesh-colored flowers resembling in size and shape those of the *Wistaria*, with a fragrance not unlike that of Sweet Peas. The flowers are followed by long pods which contain the triangular winged seeds.

I am much surprised that this tree is so little known in the United States, especially in the south. It is very easily propagated either from seeds or by cuttings, and it thrives on any well drained land of good quality. It can be grown in the north if plants are started in a greenhouse during the fall and then planted out in the spring. This tree will add variety to any garden through the summer and autumn, and when cut down by frost its roots can be dug up and utilized.

I consider the *Moringa* a very valuable addition to our list of ornamental and economic plants.

Villa City, Fla.

George T. King.

From a Foreign Creditor.

To the Editor of GARDEN AND FOREST:

Sir.—We shall be much obliged if you will inform us through your columns how an English firm can recover debts which are not forthcoming from America, whether by summons or in what manner, and whether the statute of limitation of a debt is the same as in England—six years.

Langport, England.

Kelway & Son.

[An American debtor can be summoned in any court where he can be found, either by an American or a foreigner. Practically, the best way for our correspondents to collect debts due them in this country would be to place the matter in the hands of a lawyer to manage. The statute of limitation of a debt is six years in this country.—Ed.]

A Weeping Maple.

To the Editor of GARDEN AND FOREST:

Sir.—Last summer a writer in the *Critic* made some inquiries concerning a peculiar Maple-tree which was standing in a long row of ordinary trees of the same species by the old Hopkinson place, in Bordentown, New Jersey. It was stated that this exception was a particularly large tree standing nearer the house than the others. Within about fifteen feet of it is the stump of a great Weeping Willow which was cut down many years ago. The large Maple seems to have the peculiarities of this Willow—that is, its leaves are more feathery than is usual with Maples, and its branches droop just as the Willow's did until they almost sweep the ground.

The inquiry was made whether the peculiar form of this Maple was due in any way to its proximity to the Willow. The matter was referred to GARDEN AND FOREST, but I have seen no response.

Trenton, N. J.

Q.

[It is not probable that the writer in the *Critic* had any belief in the "theory of re-incarnation" or that the Willow

had any influence in forming the Maple. But Professor A. C. Apgar, of Trenton, who visited the Bordentown tree not long after the note concerning it had appeared in the *Critic*, asked a resident of the neighborhood for a ladder in order to get a specimen of the "Weeping Maple," and he was at once told about the proximity of the Weeping Willow, which, according to the man's notion, completely explained the phenomenon. White Maples not rarely assume a somewhat drooping habit, and this tendency differs very widely in different trees. Professor Apgar writes that between the Hopkinson place and the station, which distance is not more than a length of two or three city blocks, there are three other Maple-trees which show a marked weeping habit. The one in question, however, is more decidedly pendulous than any specimen which has come under his observation. Some of the twigs, of which sketches were sent to this office, hang in as nearly vertical lines as those of any of the so-called "weeping" trees. One twig with over thirty-six inches of growth for the current year shows that the Maple is a vigorous one. Specimens of the leaves which were sent differ little from those of ordinary White Maples, although they may have been a trifle more deeply cut. In this particular, too, the leaves of this species vary considerably.—[Ed.]

The Kansas Horticultural Society.

Orchards on the Prairies.

DURING the three days' session of the Kansas State Horticultural Society, which began at Topeka on December 2d, the usual wide range of topics was under discussion, but throughout the entire meeting it was easily seen that the subject of paramount interest was that of the Apple-orchard, and especially the growing of market sorts. This was doubtless due in part to the shortage of the apple crop in the east and the presence in Kansas last fall of a host of eastern buyers who took the surplus of apples at high prices. Much had been published in state papers about the Wellhouse Orchard of Leavenworth County, and when the manager and part owner, Mr. F. Wellhouse, of Fairmount, took the floor as chairman of the Standing Committee on Orchard Culture he was plied with numerous questions relating to every feature of the great enterprise. From his replies and from additional information kindly given I gathered the following: The orchard is owned by Messrs. Wellhouse & Wheat and contains 437 acres of trees in bearing, planted in 1876, 1878 and 1879. Of the principal varieties planted Ben Davis occupies 225 acres, Missouri Pippin seventy acres, Winesap seventy acres, Jonathan forty acres, Cooper's Early White sixteen acres and Maiden Blush sixteen acres. In 1889 and 1890 of Ben Davis 370 acres were planted, Missouri Pippin 260 acres, Jonathan 120 acres, York Imperial fifty acres and Ganot twenty acres. There were planted in the older orchard a total of 52,000 trees, of which it is estimated that 40,000 are alive to-day. The heaviest loss occurred from the effects of the winter of 1884-5. With a very wet fall the trees made a late growth and went into the winter full of unassimilated sap. With the mercury at twenty degrees below zero during January many of the trees burst their bark, others were split through the trunk. Many that did not die from this injury the next season only lived a year or two longer. The loss from this cause was greatest among the Ben Davis trees, amounting to about fifteen per cent. of the whole. It will be seen that the number of trees planted gives about 119 to the acre. It is but fair to say that Mr. Wellhouse now regards this planting as too close, and their young orchards mentioned above are set sixteen feet apart, in rows thirty-two feet apart, running north and south, which will admit of thinning one-half if found desirable.

The location of these orchards is upland-prairie of average fertility, the subsoil being a red clay containing considerable sand. Mr. Wellhouse advises cultivating the land to corn till the trees come into bearing, after which he would seed to Red Clover. Stock should be kept from the orchard, especially hogs, as their tramping packs the ground, and by rubbing and rooting about the trees they do a great deal of damage. The Clover-crop is not removed from the orchard, but with a long machine resembling a stalk-cutter, but with smaller diameter, the weeds and clover are cut and allowed to remain on the ground, the object being to secure a loose, mellow soil among the trees, resembling a forest-bed as much as possible. Spraying with London Purple in the proportion of one pound to 100

gallons of water was tried last year to destroy the codling moth. A part of the orchard was sprayed twice and the rest three times; but the third application seemed to scald some of the leaves without being of any benefit.

Mr. Wellhouse has discarded, as useless for his purpose, all the spraying machines and nozzles upon the market, and he uses a tank fifteen inches deep, three and a half feet wide and four and a half feet long, slung between the wheels of a wagon. Upon this is mounted a common rotary pump, operated by means of a sprocket-wheel and chain from one of the hind wheels. This gives a positive action, starting the spray the instant the wheel starts and stopping it as quickly, avoiding the unpleasant waste and drip occasioned by the pressure from the air-chamber of the force-pump. The nozzle finally adopted is one of their own construction, having a fine slit in the casting resembling a gas-burner. This gives a broad, fan-like spray, and enables the operator to cover one side of the row of trees in driving by, at the same time managing the team. Ponds for collecting surface water to be used in spraying are constructed at convenient distances by damming ravines or draws. A man and team spray 160 acres in about five days. Adding to this the cost of poison and it brings the cost of spraying once to about fifteen cents per acre.

Everything in connection with the enterprise is reduced to the most careful system, and an accurate account has been kept of all expenses and receipts since the planting of the orchard. The actual yield of so large an orchard, over a period of eleven years, is a matter of much interest, and I am permitted to give you the following figures: In 1880, 1,594 bushels were gathered; in 1881, 3,887; in 1882, 12,037; in 1883, 12,388; in 1884, 11,726; in 1885, 15,373; in 1886, 34,990; in 1887, 33,790; in 1888, 20,054; in 1889, 11,952; and in 1890, 79,170 bushels. The last crop, it will be noticed, is more than double that of any previous year. This, at the high prices which ruled, gave a gross income of about \$50,000. The entire outlay for the year, including barrels for shipment, amounted to \$14,000, of which \$7,000 were paid for picking. This left a net profit of \$36,000, or \$82.38 an acre, which gives considerable color to the story which went the rounds of the press during the fall that the crop from many Kansas orchards this year had sold for more than the entire land was worth.

His Jonathans gave Mr. Wellhouse the best prices, bringing from \$3.50 to \$3.75 a barrel of three bushels. Ben Davis, Winesap and Missouri Pippin were contracted to eastern firms at \$3 a barrel. During the entire eleven years the Missouri Pippin has taken the lead for profit, and this year's returns placed it still further ahead. The Winesap they have not found as profitable as the other sorts, the size of the fruit averaging too small, and it is not included in their new plantations. The York Imperial they regard as a promising apple for their locality, and they are planting it quite extensively. The Ganot, a new apple originating with a fruit-grower of that name near Lee Summit, Missouri, was mentioned with much favor by Mr. Wellhouse. It is described as closely resembling the Ben Davis in tree and fruit till the latter begins to color, when it takes a much deeper color, has more yellow and firm flesh, and is generally conceded to be a better keeper. Mr. Wellhouse closed his remarks by adding, very aptly, that he was looking with a good deal of interest for the coming apple, and wanted to get some trees of it to plant.

In the general report on fruits from different parts of the state the Winesap received rather better treatment, and will doubtless continue to be planted largely as a reliable late keeper of much better quality than either Missouri Pippin or Ben Davis. Rawle's Genet, except in a few favored localities, was declared to crack and rot badly on the trees, besides keeping poorly after it was gathered. It is being largely discarded.

An instructive paper prepared by Professor L. H. Bailey, of Cornell University, entitled "Causes Affecting the Longevity of Orchards," was read by the Secretary. The ground taken was that the supposed greater longevity of old seedling orchards in the east was more apparent than real; the trees which attracted attention being the few fittest to survive, while the many which perished prematurely escaped notice. The popular cry against root-grafting on stocks from pomace seed, as tending to deteriorate the vitality of varieties, had no foundation in fact. The even stand and uniform character of trees in modern orchards showed that the cion either dominated the stock or had become self-rooted. The short life of many orchards in the west must be accounted for by the fact that they were in a prairie region beyond the limits of natural forest-growth.

The general opinion of the members of the Society seemed to be that while the older orchards of the state show that they are destined to be short lived, we should not be discouraged by this fact. With the abundance of comparatively cheap land in

the state and the small outlay needed for planting, young orchards should be set as fast as the old ones show signs of failing, and the supply of vigorous, bearing trees kept up.

It was thought that the rapid development of the country to the north and west beyond the range of profitable Apple-culture must give a market for Kansas apples at paying prices for a long time to come.

Notes.

Another use has been found for the bark of the Cork Oak. It seems that in Europe "cork concrete," made of ground cork mixed with a cement that is called "liègine," is somewhat extensively used in building. It is said to be as strong as the porous terra cotta which is known as "terra cotta lumber," to be better in its capacity for holding nails, and also as a non-conductor of sound, and almost equally fire-proof.

We have received a photograph of a superb specimen of *Phalenopsis Schilleriana* grown by John Hosken, Esq., Q.C., The Dale, Toronto, Ontario. The plant carries seventy-five fully expanded flowers. A visitor who has seen it states that the flowers show great substance and breadth of petal, while the leaves were nearly two feet in length. The plant grows at will in a perforated pot, and a large tank under the bench near it is constantly full of water.

The annual meeting of the American Forestry Association will be held on Tuesday, December 30th, at the Department of Agriculture, Washington. At the morning session officers for the ensuing year will be elected and general business transacted; in the afternoon there will be another session for discussion and business; and in the evening a session will be held at the National Museum conjointly with the American Economic Association, where papers on the proper treatment of forests on the public lands of the United States will be read and discussed. It is particularly desired that as many of the Vice-Presidents as possible will be present.

A fine mass of the beautiful and fragrant, rose colored flowers of *Luculia gratissima* was sent to a recent meeting of the Massachusetts Horticultural Society from Mr. Hunnewell's gardens at Wellesley. This handsome evergreen shrub is a native of the temperate regions of the Himalaya and has long been a favorite in English gardens. It is particularly valuable because it flowers at a season of the year when flowers are scarce. *Luculia gratissima*, nevertheless, and this is true, too, of the second species of the genus, the still more beautiful *L. Pinceana*, is very rarely seen in this country. Both species can be successfully cultivated in pots, although they do best when planted out in a border in a moderately warm greenhouse.

Popular Science News gives a report of the meeting of the British Association for the Advancement of Science, held recently at Leeds, from which it appears that a large part of one day was devoted by the biologists to a consideration of the subject of teaching botany in schools, introduced by an able paper by Professor Marshall Ward. Botany, he urged, should be taught, not in order that names and facts may be committed to memory, but that habits of accurate observation may be acquired by the pupil, and great principles and laws grasped which in future may be applied under any special conditions. In these views he was supported by the eminent biologists present, who, one and all, agreed that it is time to leave the blind worship of facts, and, instead of measuring a scholar's progress by the amount of dogmatic information imbibed and put into an examination paper, to look to his understanding of the relation between facts and the intelligence with which he describes what he sees.

A *Tribune* correspondent writes that 10,000 tons of fresh, dried and canned fruits have been sent overland by rail from California during the season, and this enormous amount does not include what went by express. As much of the finest perishable fruit was expressed, this probably amounts to 100 car-loads. The value of these overland fruit shipments is roughly estimated at \$10,000,000. Of prunes California shipped 15,000,000 pounds, and of raisins 40,000,000 pounds. Four thousand car-loads of oranges will be sent east this winter, an increase of 800 car-loads over last season. The first car-load shipment of oranges this season went from northern California, where five years ago it was declared that Oranges could not be grown except in gardens protected by hedges. This initial shipment came from Oroville, Butte County. A new feature this year is the shipment of early winter vegetables to the east,

the railroads having made a favorable rate. Especially in Los Angeles and other southern counties this promises to be a great industry.

It is not generally known, says a writer in *Nature*, that the Chinese grow the *Chrysanthemum* as a standard tree, especially for selling. They graft it upon a stalk of *Artemisia*. There is a species of *Artemisia* that grows wild and covers the waste ground round Pekin; it springs from seed every year, and by the autumn attains to a tree eight to ten feet high, with a stem one and a half inches thick. The Chinese cut it down, and, after drying it, use it as fuel; the small twigs and seeds are twisted into a rope, which is lighted and hung up in a room to smoulder for hours; the pungent smell of the smoke drives out the mosquitoes. This plant, after being potted, is cut down to about three feet, and used as the stock, the twigs of *Chrysanthemum* are grafted round the top, and it quickly makes a fine tree, the flowers grow and open, and as the stock soon withers the whole tree dies, and folks say, "Another ingenious fraud of the Chinamen." A favorite style of growing *Chrysanthemums* is in the shape of a fan, with eight or ten flowers in different parts of it. If the flowers are not grown on the plant, they are tied on, which also does for selling. The winters in Pekin are very cold and last about four months, and having no glass houses the Chinese gardeners do not have the chance of producing such a variety or such fine flowers as their European brethren, but in the case of *Chrysanthemums* they have many curious and beautiful varieties.

M. Charles André, in *Le Journal des Orchidées*, gives an account of his experiences when on a botanical expedition by the shores of the River Amboan, which, though interesting to read when safe at home, gives a good idea of the unexpected dangers often incurred by botanical collectors. M. André was in search of *Celogyne asperata* and happened to be in a Dyak hut when the natives were sorting rice preparatory to sowing it. In the evening a noisy procession entered the hut, and the females who were among them laid with much ceremony large bouquets and garlands of the longed-for Orchid on and around the stores of rice. Such was the quantity of the blooms that the perfume was so powerful as to drive the explorer out of the house to spend the night in his boat. He afterward heard that seed-time as well as harvest is an important season to the natives, who are dependent on their crops, and that he had witnessed rejoicings caused by the abundance that year of the *C. asperata* blooms, which were believed to herald an equally fertile harvest. When, some time later, M. André returned to the spot with (among other treasures) a load of the all-important Orchid, he found himself the subject of passionate grief and hatred, and that his only chance of safety was in a generous distribution of money and tobacco and a speedy flight. He had, in the opinion of the Dyaks, committed an act of sacrilege in gathering plants sacred to them, and whose lives they believed were in some way connected with their own.

In "The Resources of Southern Oregon," collected and prepared by the Southern Oregon State Board of Agriculture and recently published at Salem, there is an interesting account of the forests and forest-trees of southern Oregon from the pen of Mr. E. W. Hammond, of Wimer. The forests of southern Oregon are composed chiefly of conifers, containing some of the noblest and most valuable trees known to man, and although these forests do not occupy comparatively a very large area, being confined principally to the Cascade range of mountains, with an average width of about thirty-five miles, and to the coast ranges with an average of about thirty miles, they contain vast quantities of timber. The whole area covered in the state by these two forest-regions Mr. Hammond estimates as 16,000 square miles. "These large forest-areas," he says, "secure an abundant flow of water in the streams both in summer and winter, even in the driest season. Their simply commercial value, if the timber should be cut from them and sent to market, would have been sufficient to have paid the national debt twice over at the highest figures—that is, at \$10 per 1,000 feet, the lowest price at the mills of the coast pine and fir lumber, it would amount to \$4,000,000,000, for it is estimated by competent judges, after a careful survey of the whole region, that the quantity of the merchantable timber yet standing in the two great forests of the state amounts to no less than 400,000,000,000 of feet." Mr. Hammond's note of warning against the wanton and useless destruction of these forests now going on cannot certainly be too often or too loudly sounded. The welfare of the north-western states depends more upon the preservation of these forests than upon any other one thing.

Country Roads.

DURING the autumn which has just passed a correspondent of the *Hazleton* (Pennsylvania) *Plain Speaker* gave a description of a typical country road which attracted much attention. The road in question climbed slowly up a mountain with a grade which made drainage perfectly easy. In the County of Luzerne conglomerate rock and red shale abound and furnish such good material to pack hard under travel that there is no excuse for anything less than a smooth wheelway. And yet it was said that the road was rendered almost impassable in October by half liquid mud, in which the wheels of a light wagon sank to the depth of eight inches. This was not because the road had been left to itself, but because it had been laboriously repaired with cart-loads of black mould and clay scooped out from the road-side and shoveled upon the track. Of course, the road-bed became a continuous mass of mud after every rain and a stretch of blinding dust in every dry time, and as cold weather comes it will freeze into iron ridges, and nothing but the merciful snow will cover up its iniquities. Unfortunately, there is nothing singular about this Pennsylvania highway. All through the United States our people drive through mud and dust, to their discomfort, a great portion of the year; and yet the annual cost of repairing vehicles, added to the value of time wasted and the expense of extra horse power used in hauling loads, would give us, as a rule, passable highways.

Now a road that is permanently good must be properly made to begin with, and in the second place proper measures must be taken to keep it in constant repair. But no such attention has been given to the construction or maintenance of one mile in a thousand of our ordinary country roads. There was originally some excuse for this. The first roads were built when the country was thinly settled and anything like the expense necessary for a well constructed bed with adequate drainage was not to be thought of. Perhaps, too, the old plan of mending the roads, under which the farmers of a district assembled with hoes and

shovels to do their road-mending all at once for the entire year was a most natural and economical plan. But in the older settled portions of our country, where the population is no longer scattered, no reasonable excuse remains for making a poor road or for tolerating improper road-mending.

It is encouraging to find that public opinion is making strenuous demands for reform in this direction, and in addition to improved road laws which were passed in half a dozen states last winter, we may probably hope for still more effective legislation in twice as many states at the next meeting of their Legislatures. Without stating here any of the fundamental principles which should govern the construction of roads, it is plain that such work should only be done by experts trained to the profession. The roads which have been famous for generations were built by engineers on scientific principles, and the fact that in several of our agricultural colleges a course of road-engineering is obligatory indicates a hopeful direction in current thought. The fact, too, that in so many states the old district system has been abandoned, and that skilled officers have been appointed to take charge of the roads of an entire district, is certainly a great step forward; and this, with the available machinery at command, which is multiplying in every part of the country, and the inspiring example which every mile of good road exerts on its vicinity, makes it probable that our improvement in this matter will be more rapid than we dared to hope a few years ago.

In the state of Pennsylvania this road question has been a matter of such special agitation that a legislative commission has been examining the subject in all parts of the state, and they have practically agreed upon an act to be introduced at the approaching session of the Legislature. By the terms of this act three commissioners will be selected in each township who will have the power to appoint and pay road-masters. Farmers who choose to work out their taxes must notify these commissioners before the 13th of April; they will not be allowed to work at their convenience, however, but will be required to report at such times and places as are designated by the road-masters, and on failure to comply with these terms their tax will become payable in cash. This to a certain extent puts road-construction and road-mending under something like expert control. The next provision of the act is that in addition to the annual mending of the roads a certain portion of the money collected for this purpose shall be set aside for permanent improvement. Wherever one mile in a township has received such thorough construction, that is, wherever the road has been built on a stone or gravel foundation with a covering of such metal as is approved by the county engineer, the county will be required to build an additional mile of permanent road in the same township, and the state will be required to construct another mile. The Attorney-General of the state announces that there is no legal objection to the appropriation of state funds to the permanent improvement of roads, and it is plain that local enterprise will thus be encouraged. The state authorities with those of the county and of the township will be placed in competition, and there is no reason to doubt that the miles of good road in the state will be rapidly multiplied.

Meanwhile, in order to increase the general knowledge on this subject, the University of Pennsylvania has offered a prize of \$500 for essays on road-construction and road-mending, and the publication of the most useful of these essays is promised at an early date. Such a book ought to prove of great value just at this time if the state is to inaugurate anything like a general improvement in its highways. The initial expense will, of course, be considerable, but it is believed that the state will have ample funds to meet the townships and counties in competition. That these improvements will pay for themselves in a few years there can be little question. In a recent number of the *Philadelphia Inquirer*, which contains a clear statement of the whole project, there appears a quotation from a paper read before the State Board of Agriculture by Mr. S. R.

Downing, one of its members, in which he shows that if drainage and repairs to the roads are made at the proper time, it will save each tax-payer under the present system from twenty-five to fifty per cent. of road taxes. This means that the present labor tax is enormously wasteful. The cost of maintaining the average township road in the eastern counties of the state is estimated at \$1,500, of which \$1,200 are spent in wages for work done late in the spring, to suit the convenience of farmers, after gulleys have been deepened and much destruction has been allowed by this neglect. It is further shown that four men by draining and filling at such times as their work is needed could keep the same roads in repair by eight months' work at a saving of \$410—that is, a land-holder who pays \$20 road tax under the present plan would save \$6.75 under the cash plan, or if the service lost to the farmer is added, the total waste will be more than \$10 out of every \$20 of taxes paid.

Bad roads are expensive roads; improper maintenance is a shameful extravagance; in too many instances the men who are paid for repairing roads should in justice be fined for obstructing them. Any revolution in law or practice which will ensure to our people such roads as are common throughout Europe will materially lessen the expense and add to the comforts and pleasures of country life.

The North Woods Thirty-six Years Ago.

WE chanced not long ago upon a book called "Hills, Lakes and Forest-Streams, or A Tramp in the Chateaugay Woods," written by S. H. Hammond, and published in 1854. The author's name is not now familiar, and his work has no great literary interest, being a simple account of a summer outing, written by a man who evidently enjoyed Nature and a wild life keenly, but had no desire to collect statistics of any sort or describe the scenes he saw in anything more than a general way. But his words have, incidentally, great documentary value, as proving how short a time it has taken to bring the Adirondack woods into their present condition of semi-ruin.

"If," he says in the preface, "the reader will lay before him a map of the counties of Clinton, St. Lawrence, Franklin and Essex, and, beginning at the Chazy Lake, run his eye thence along to Bradley's Lake, then to the Chateaugay, then west to Ragged Lake and Indian Lake and so down through the series of small lakes to the St. Regis and then to the Saranacs, and down along again through three small lakes to the Racquette River, and then down that beautiful water-course to Tupper's Lake and to Long Lake, . . . he can trace out a circle of some 200 miles in circumference enclosing natural scenery the most wild and romantic, lakes and rivers the most beautiful imaginable. I was out there several weeks in the woods, along the streams and floating on those beautiful lakes, and saw during that time no face of a white man save that of my guide." In short, when this book was written all this "broad sweep of country containing millions of acres was a perfect wilderness." That was only thirty-six years ago. What is this country now? From Upper Chateaugay Lake, only a few miles south of the St. Lawrence, where the banks have been wholly stripped of trees by the charcoal-burners, to the southernmost limits of the area described, devastation has made its way—here total, there as yet but partial, but everywhere sufficiently apparent to mean distress to the eye of the lover of Nature, and imminent danger to the mind which knows the value of our water-courses and their intimate dependence upon the forests of elevated regions. Thirty-six years ago the traveler had to construct his own canoes on lakes where now tourists swarm by the hundreds, where the railway whistle may be heard, and where the lumberman and charcoal-burner are ubiquitous, an axe in one hand and a torch in the other. Ignorance, carelessness and greed have worked hand in hand during the life of one generation only, yet the wreck they have wrought no statistician can compute and centuries of the un-fettered ministration of Nature could not undo.

When we read of the primeval Adirondack forest in those old journals, where the experience of the first missionaries is embalmed, we do not think of it as a possession which once was ours. It seems to have belonged to far-off ancestors for whose ill deeds we are not responsible, and whose aims and methods, we fondly fancy, were inferior in intelligence to our own. But when we see that this primeval forest stood intact

thirty years ago we begin to realize our responsibility for past sins, and, which is still more important, we gain a fresh sense of future danger. Such agencies as have been active in this forest do not carry on their work in simple arithmetical progression. If a certain amount of damage is done during one year, the next year will see, not a similar, but a vastly greater amount. If thirty years have accomplished the ruin we now behold, thirty more years, with the same agencies at work unchecked, will more than suffice to sweep the Adirondack forests off the face of the earth—to put them in the same category as those so-called forests of England, where to-day sees only wide wastes of underbrush and an occasional isolated Oak or Beech. A letter from an American traveler which we read last summer described a drive in the south of France near Nimes which, according to the map, traversed a "forest" for miles and miles. "We could not exactly agree about it when the day was over," said the writer; "my wife insists that the forest contained seven trees; but she is an optimist by nature—I only counted six." This sounds like farce, but it is simple truth. And if present methods of procedure remain unchecked there will certainly be vast districts of Adirondack forest which, thirty years from now, a traveler may truthfully describe in a similar way.

The Autumn Flora of the Lake Michigan Pine Barrens.—III.

THOUGH the Sunflowers have mostly disappeared from the barrens, two of them are still found upon the ridges, *Helianthus divaricatus* and *H. occidentalis*. The former has a rough stem and leaves, and rather small flowers. The latter has an odd appearance for a Sunflower, by reason of its leaves being mainly near the root, the stem being nearly naked above, giving to it a scape-like aspect. It is not seen in as great numbers as the former.

Of *Prenanthes*, three species may be found in favorable localities. Among the low bushes in the richer ground *P. altissima* and *P. alba* are not uncommon, and in considerably drier localities *P. racemosa*. In the companion genus, the common Hawkweed for September, is *Hieracium Canadense*, growing like most of its kind in the dry grounds.

Two *Polygonums* may be deemed specially characteristic, both small and of slender but erect habit, with slender branches and very narrow leaves. They are *Polygonum tenue* and *Polygonella articulata*. *Polygonum tenue*, though rarely more than a foot in height, has long, simple branches more or less provided with small white flowers. The *Polygonella* is commonly of about the same height, but is sometimes taller. Since the leaves become disjointed and fall off it has a naked look. The erect branches are abundantly furnished with small, but yet showy flowers, as they are often very bright colored. In the barrens they vary much in color. The tints run from red through rose and flesh color down through pale pink to white. Some years white will be the predominating color, or white tinged with pink; in other years white will scarcely be found, the rose shades characterizing the flowers. Those which appear latest in the season seem to have the brightest colors. Both plants succeed in the driest locations, where the sands may, at the time they are in bloom, bear few plants besides them.

Lobelia Kalmii continues to blossom in the damp sands during the early fall, the smooth and slender stems showing a spike of pale blue but delicate little flowers. In the adjoining dryish ground will be seen specimens of *Buchnera Americana*, a taller plant, with an erect stem, generally without branches. It is a rough plant, and has a spike of small but deep blue flowers raised above the sparse grass amid which it is apt to grow. But it, like the *Lobelia*, is more characteristic of the late summer flora.

A papilionaceous plant yet persists in flower by the shore of the lake, though in other localities in seed or beyond that stage. It is our most common Prairie Clover, *Petalostemon violaceus*. The dense spikes of violet flowers, though much less abundant, are as complete as they were earlier in the season. It is established everywhere upon the sand ridges, and its foliage of fine and pretty leaflets keeps fresh and green till late in autumn, yielding only, like *Artemisia*, to the hardest frosts. Its form and habits, especially when close to the shore, are quite different from what it takes in the grassy prairie, where its natural home is deemed to be, and where it is single-stemmed, or nearly so. But in the sands it strikes downward with a strong, branching root, sometimes nearly an inch in diameter at the crown, the size corresponding to that of the plant. From this root rise several stems (the most I ever counted, twenty-six), forming a roundish bunch that may measure a

foot and a half across. Having this habit, few plants when it is in full bloom on the nearly naked sands are more striking than this mass of violet color. It crowds down to the shore nearly as far as the waves will let it, and attains its greatest vigor on the lakeward side of the ridge of sand which skirts the water. If the same effects could be reached by cultivation it would be a very ornamental plant both from flowers and foliage. The sand is almost purely siliceous, being carried away by car-loads for use in the best masonry as the "sharp lake sand" of the architect and builder. But this sand, at least near the surface beside the shore, is not devoid of organic matter, though in such a finely divided condition as to mostly escape detection by the eye. But dead fish and vegetable matter are continually washed ashore, and their decay must furnish nourishment to plants which grow where they have lain. They have plenty of room in which to grow, and from their location are supplied with considerable moisture, both by capillary action from the saturated sand below them and by the moist air rising from the neighboring waters. Besides, the free play of the winds around the plants and their exposure to abundant light, almost dazzling as reflected from the sand in the full blaze of the sun, doubtless have much to do with the symmetrical grouping of the stems. In fact, this roundish or bunch-like habit, and this tendency of plants to throw out several stems from a common root, is characteristic of several others near the shore, which grow there exclusively or crowd down to it from stations farther off, where they may be nearly or quite single-stemmed, and such illustrations of this may be instanced as *Prunus pumila*, *Cnicus Pitcheri*, *Solidago humilis*, *S. nemoralis* and *Artemisia Canadensis*. The plants are not crowded, each has plenty of room, and, like trees in the open fields, they freely develop in all directions, the forces acting on them being in equilibrium.

Another lingerer from the summer may still be seen in considerable quantities upon the ponds during a week or two of September—the White Water Lily. The only one I have detected here is *Nymphaea reniformis*.

It is now the proper season of another showy plant, *Physostegia Virginiana*. Its natural home is in rather moist and usually grassy ground. It has an ample spike of long flowers, with an inflated, trumpet-shaped tube. They are pale rose, more deeply colored on the upper side by darker lines, and stand out horizontally from the stem with gaping mouths. In the bud these form four rows, one on each side of the square stem, but as they expand they turn toward the sun so that the spike is at length one-sided. It is a very smooth plant, with thick, dark green leaves, and is handsome throughout.

Some of the Dodders continue in flower, attracting attention by their tangle of orange-colored, thread-like stems, bearing numerous clusters of pale or colorless flowers of a delicate cellular texture. *Cuscuta Gronovii* and *C. glomerata* are the principal ones. The former is parasitic on herbs and small shrubs in damp, shaded locations, the latter almost always on *Compositæ*, especially Golden-rods, in more open situations. In the fruiting stage it is conspicuous for the rope-like coils around the stem of the host-plant, made by the dense and continuous masses of globular capsules.

Growing among the low shrubs, beside the sloughs and in the moist land a tall Thistle is common, *Cnicus muticus*. It has long and slender branches, ending in a handsome, middle-sized head of bright purple flowers. The viscid scales of its compact and shapely involucre are not the least notable of its features. Its leaves are few and distant, its peduncles long and naked. When it attains a height of five or six feet, as is often the case, raising the many heads of flowers far enough above the shrubs to obtain a background of green from the stunted Pines near at hand, it presents a pleasing picture, and this Thistle will not be despised or soon forgotten when seen in its native settings.

Some tall Grasses now in flower on the sand ridges must not be overlooked. They are *Andropogon furcatus*, *A. Virginicus* and *Chrysopogon nutans*. The first is about three feet high, the last two usually from four to six feet. All are of a glaucous green hue, and provided with long, narrow leaves. The two taller are the most striking in appearance, the culm of the *Andropogon* ending in a diffuse panicle of digitate spikes, feathery, with white, silky hairs; that of the *Chrysopogon* in a graceful, oblong panicle, with shining, russet brown hairs. Though the stands of the *Chrysopogon* are distant from each other, and the Grass is scattered along the open ridges, there are enough of them to give character and animation to the scene, especially when the tall stems are waving in the wind. As an ornamental Grass in the Pine-barrens, this "golden bearded" one takes precedence of all that grow there at any season of the year. Another curious Grass is met with more

commonly on the higher ridges, being particularly characteristic of the thinly wooded dunes, *Aristida tuberculosa*. It is but ten to twenty inches high, and is remarkable for its flowers bearing three long awns twisted together at the base and widely divergent above. As they point every way, when in fruit the stem has a kind of chevaux de frise look from whatever side it is approached.

I have noted only the more striking features of the autumnal flora of the Pine-barrens. It is one of the four periods into which the season of flowers may be divided, noticeable changes occurring so as to distinguish them from each other. A kind of pause takes place, and then a different set of plants flourishes, giving to the flora quite a distinct facies. These appearances and changes are evidently due principally to variations in heat and moisture. The four periods may be called that of spring, from the opening of the season till about the 1st of June; the early summer, lasting from four to six weeks from the close of the former; the summer, continuing through the warmest and usually driest part of the year, the season of occasional showers, and ending about the last of August; the autumnal, or remainder of the year, as described in these articles.

Englewood, Chicago.

E. J. Hill.

Basket-Work of the North American Indians.—I.

PROBABLY the most generally diffused handicraft among our Indian tribes is that of basket-making in its various forms; it is that which subserves the most useful purposes, and in which they have acquired most skill. This native art, at first simple and rude to meet the requirements of savage and nomadic life, has been steadily growing and improving and has attained remarkable ornamental developments.

The collection of native basket-work in the National Museum is exceedingly interesting in the number and diversity of its types, a mere enumeration of which is only admissible here: dishes and plates, bowls, roasting-trays, jars and water-bottles, mats, wallets, wall-pockets, hats (often of exquisite pattern), hoods for papposes; baskets, of forms innumerable, to winnow seeds, carry luggage, store grain, keep fruit, etc.

The interest of the botanist is naturally aroused in the material used by the various Indian tribes in their basket-work. I have been enabled to determine a large proportion of the plants thus used in North America;* many others, of which I have no knowledge, are doubtless likewise employed, and perhaps some of the readers of GARDEN AND FOREST will kindly contribute additional information on the subject, so that the list may be made as complete as possible, even to the extent of including the material used by civilized people.

Let us begin with Grasses. In a valuable paper by Dr. O. T. Mason in the Report of the National Museum, 1884, we read that the natives of the Aleutian Islands make their mats and baskets "of the fibre of the Elymus treated as hemp," and that the marvelous nicety of this grass-weaving is worthy of all praise. The species of Elymus referred to are *E. mollis*, *E. arcnarius* and *E. Sibiricus*. The "Wild Wheat" basket-material of the Chilkah Indians may be one of these.

A *Sporobolus* is mentioned in the same paper as used by the Tule-River Indians of California, but there seems to be no species of that genus, in that locality, suitable for the purpose; it is not unlikely that *Vilfa depauperata* is meant, a plant with long, filiform and flexuose culms, much sought after by Mexicans for stuffing their large leathern aparejos, a purpose to which its toughness and elasticity specially adapt it ("Botany of California," ii., 267).

The Cane (*Arundinaria macrosperma*) of the southern states furnishes the principal material for the basket-making of the remnants of the Cherokees, Choctaws, Creeks, Chickasaws and Seminoles. The Choctaws specially excel in its use, and their little baskets, variously colored, are offered for sale in several southern cities.

The New England Indians, especially the Penobscots, make an extensive use of the Holy Grass (*Hierochloa borealis*). Its long radical leaves become strongly involute in drying, forming flexible threads, which are braided into fine strips, and these are woven into baskets and other pretty fancy work. I have also found braids of Holy Grass in a camp of the Crow Indians on the Yellowstone, but did not learn how they were used. The delicate and lasting fragrance of the dried leaves gives them an additional, and perhaps not their least, merit.

Other Grasses, species of *Spartina*, *Calamagrostis*, etc., suggest themselves as particularly suitable where length,

* My grateful acknowledgments are due Dr. C. E. Woodruff, U. S. A., for much interesting and valuable information concerning the Hoopa and Klamath Indians, whose basket-work, in variety of forms and perfection of finish, is probably not excelled in the country.

toughness and flexibility of culms are the chief requirements, but I have no knowledge of their having been used.

In a study of the subject one first thinks of Osiers or Willows as the ordinary and proper material, but it is well known that our Willows do not possess the softness and pliability which make several species of so much economic importance in Europe; even when cultivated in this country these species become woody and hard. From all the information within my reach, I am led to believe that the native Willow most used in this country, at least west of the Rocky Mountains, is *Salix sessilifolia*. From the region of the Hoopa and Klamath Indians of northern California and southern Oregon, to that of the Papagos of southern Arizona, this plant furnishes one of the best materials for the warp of basket-work. Young shoots two or three feet long are cut in the spring or early summer, stripped of their bark and dried; they are soft and remarkably flexible, sometimes quite tenuous, almost filiform. This species deserves attention as one most worthy of cultivation for the production of valuable osier. In order to keep it well pruned down and provoke new growths of young, tender shoots the Indians of northern California set fire to the woods, an operation likewise intended to improve the Hazel-nut, another highly esteemed basket-plant.

Other native species of *Salix* are, or have been, used, such as *S. cordata*, *S. sericea*, *S. petiolaris* in the eastern and middle states, the last two of real value; *S. lasiandra*, *S. lasiolepis* and *S. laevigata* in the western and Pacific states. Of the last named only the roots are used by the Hoopa and Klamath Indians.

Dr. E. Palmer states (*Amer. Nat.*, 1878) that along the Colorado River a Willow, not specified, yields an abundance of long, soft bark from which the Indians make rope, twine, sandals and mats. Willow-bark is also used by the Tule-River Indians of California.

Most species of Poplar have soft, pliable and tolerably tough rootlets well adapted to the requirements of basket-making. Those of *P. trichocarpa* are much used, entire or split, by the Indians of northern California for the brown work of the woof of their hats and baskets. Whoever has seen the petticoats, made of the inner bark of the Cottonwood (*P. Fremontii*), worn by the squaws along the Colorado River, must have realized the possibility of utilizing the same material, as well as that of the allied species, *P. monilifera*, in the manufacture of many household utensils.

The rootlets of Alder (*Alnus rhombifolia*) and probably others furnish brown threads much esteemed by the Indians of California and Oregon.

The young flexible twigs of the California Hazel-nut (*Corylus rostrata*, var. *Californica*) are almost in as great demand by the Indians of California and Oregon as the branches of *Salix sessilifolia*, these two plants making up most of the warp of their basket-work. Hazel-nut-twigs are also much used in binding fish-dams.

One of the best known basket-plants is the Trefoil Sumach or Squawberry (*Rhus aromatica*, var. *trilobata*), a shrub widely distributed from the Missouri through the Rocky Mountains to the Pacific. It is one of the chief materials of the Apaches, Navajos and other tribes in southern California, Arizona, Utah and New Mexico. The twigs are soaked in water, scraped and then split. The baskets are built up by a succession of small rolls of grass, over which the twigs are firmly and closely bound; according to Dr. E. Palmer, they "are very durable, will hold water, and are often used to cook in, hot stones being dropped in until the food is done" (*Amer. Nat.*, 1875). I am informed that the Poison Ivy of the Pacific coast (*R. diversiloba*) is also a basket-plant, but it is quite possible that this species is confounded with the preceding.

The Indian Hemp (*Apocynum cannabinum*) has a strong fibrous bast easily stripped off, and from which many tribes from the Great Lakes to the Pacific, but specially those of the Great Basin, have from time immemorial made rope, lariats fishing lines, bags, mats, baskets, belts, etc.

The Sioux Indians, I believe, never practiced the manufacture of any but the coarsest kind of basket-work, and in this the bark of the Elm (*Ulmus Americana*) takes a prominent part. The Red-Osier Dogwood (*Cornus stolonifera*), so abundant in their country, is not used in basket-work so far as I know, notwithstanding its pretty purple, osier-like shoots. It is, however, stated by B. S. Barton that the young shoots of an allied species, *C. sericea*, were formerly used to make coarse baskets.

Of vines, the California Grapevine (*Vitis Californica*) should be noted; its stems, slender, flexible and strong, make good ropes and may be twisted into various household articles. The Supple-Jack (*Berchemia volubilis*) also suggests itself in this connection.

Fort Buford, N. Dak.

V. Havard.

New or Little Known Plants.

Clematis paniculata.

THIS is a stout, vigorous plant with long, climbing, woody stems, which is widely distributed and very common in nearly all parts of Japan, and occurs also in central and northern China. It is allied to our common Virgin's Bower and to the European *Clematis Flammula*. The leaves are long-petioled and are composed of three ovate, pointed leaflets, obliquely cordate at the base, with entire margins and prominent veins. The flowers are produced in long axillary panicles; they are white, fragrant, one and a half inches across, with narrow, obovate, acute sepals. They begin to open toward the end of August and continue to appear for nearly a month, being succeeded by heads of fruits furnished with long, plumose, silvery tails which are almost as ornamental as the flowers.

*Clematis paniculata** was discovered by Thunberg, the Swedish botanist, who resided in Japan from 1773 to 1779. It is stated by Nicholson in "The Dictionary of Gardening," on what authority I do not know, as this species is not mentioned in the second edition of Aiton's "Hortus Kewensis," that it was introduced into England in 1796. Its early introduction is possible, as, according to Maximowicz, it was figured by Houttyn, a Dutch author, whose work on woody plants, to which I have not access, was published toward the end of the last century. But whether this Japanese plant was introduced early into European gardens or not, it has certainly never made any great figure in them, and I can find no portrait of it in any of the principal horticultural or botanical periods. It was included, however, in the catalogue of plants cultivated by Monsieur Lavallée in his Arboretum at Segrez, and three years ago I found it in the garden of the Paris Museum.

Clematis paniculata was probably introduced into the United States by Thomas Hogg through the Flushing nurseries, as it was received at the Arboretum thirteen years ago from Mr. Parsons. It has also been sent by the Agricultural College at Sapparo and by James Veitch & Son, of London, under the name of *C. Flammula robusta*, and by Spath, of Berlin. The credit of making this fine plant known in American gardens is due, however, to Mr. Edward O. Orpet, at one time foreman of the Hardy Plant Department in the nurseries of Woolson & Co., of Passaic, New Jersey. "When I came to Passaic," Mr. Orpet writes, "there was an old plant there which had been brought originally from Japan among other plants, and every September it was a grand sight. It did not always ripen seed, and cuttings would not root unless taken in heat in the spring. I at once thought that grafting might be tried, and as *C. Virginiana* grew wild in quantities in the neighborhood, this suggested itself to me as a substitute for *C. Vitalba*, used by the English growers as a stock for the garden varieties of *Clematis*. I tried a few; the plants took easily, were potted in six-inch pots, planted out in May, and by September had grown ten feet high, with numerous shoots which flowered right down to the ground-level.

"So much for *C. Virginiana* as a stock, but I soon found that it was hard work taking out the roots from the swamps where it grows, and as we had a number of plants of *C. Stans* in the garden I tried this, and the stock (root only) united with the cion in two weeks; and the plants made far better growth from the first. Even the large-flowered Clematises do much better when grafted on *C. Stans*, the callus being much more readily formed than when *C. Vitalba* is used. Roots the thickness of a Wheat-straw are the best, and when grafted the plants should be planted in small pots and plunged in sand in a grafting-case or a frame."

* *Clematis paniculata*, Thunberg, *Trans. Linn. Soc.*, ii., 337.—Miquel, "Prol. Fl. Jap.," 139.—Franchet & Savatier, "Enum. Pl. Jap.," i., 1.—Maximowicz, "Mél. Biol.," ix., 595.—Franchet, "Pl. David.," 12.—Forbes & Hemsley, *four. Linn. Soc.*, xxiii., 6.

C. crispa and *C. Virginica*, Thunberg, "Fl. Jap.," 239 and 240. "*C. Vitalba* e. Japonica, Houttyn, 'Houtkunde,' t. 55, f. 2."

Clematis paniculata is an ornamental plant of great value. It is vigorous and very hardy; it grows rapidly, and flowers later in the season than the other species which resemble it, and at a season when few woody plants are in flower. The fruit is very handsome and retains its beauty until winter, and its foliage turns to rich colors in late autumn. The plants sent to the Arboretum as *C. Flammula robusta* are sometimes killed back in severe winters, and are less hardy than those raised from seeds gathered at Sapparo. It is from one of these that Mr. Faxon has made the drawing which is here reproduced.

C. S. S.

SOBRALIA SANDERÆ, Rolfe, is a very handsome species introduced from Central America by Messrs. F. Sander & Co., of St. Albans. The flowers are larger than in *S. leucoxantha*, and without the orange markings in the throat, but paler and somewhat smaller than in *S. xantholeuca*. The segments are three and a half inches long and pale sulphur-white, with the throat of the lip of a bright clear yellow.—*Gardeners' Chronicle*, November 1st, p. 494.

CATTLEYA LINDENI is a beautiful form allied to *C. × Hardyana*, and probably a natural hybrid between *C. gigas* and *C. Dowiana aurea*. The sepals are pink, the petals lilac-rose with lighter veins, while the lip is very rich crimson, with two

Fig. 82.—*Clematis paniculata*.—See page 620.

New Orchids.

ANGRÆCUM HENRIQUESIANUM, Rolfe, is a very neat and pretty little species from the island of St. Thomas, West Africa, which flowered in the Botanic Garden of the University of Coimbra, Portugal, during 1889, and at Kew during the present year. It is closely allied to *A. bilobum*, but is a much smaller plant in every respect.—*Gardeners' Chronicle*, October 25th, p. 466.

CIRRHOPE TALUM MASTERSIANUM, Rolfe, is an elegant little Cirrhopetalum introduced from the Dutch Indies by Messrs. Linden, L'Horticulture Internationale, Brussels, during the present year. It is allied to *C. gamosepalum* of Griffith, a species probably not in cultivation. The flowers are buff, variously marked with reddish brown, and with a purple-brown lip. It is described and figured in *Lindenia*, vol. vi., p. 33, t. 245.

lateral yellow blotches in the throat. It was exhibited by Messrs Linden, L'Horticulture Internationale, Brussels, at a meeting of the Royal Horticultural Society on October 28th last, when it received an award of merit.—*Gardeners' Chronicle*, November 1st, pp. 507, 508.

MASDEVALLIA O'BRIENIANA, Rolfe, is a tiny little species about two or three inches high, which appeared in the collection of Mr. R. I. Measures, of Camberwell. It is closely allied to *Masdevallia simula*, but has much larger flowers, which measure half an inch in length. The flowers are light yellow, spotted with maroon, and very pretty.—*Gardeners' Chronicle*, November 8th, p. 524.

ONCIDIUM LEOPOLDIANUM, Rolfe, is a noble and handsome Oncidium, introduced by Messrs. Linden, L'Horticulture Internationale, Brussels. It belongs to the Cyrtorchilum section, and is allied to *O. corynephorum*, Lindl. The peduncle is said to

attain a height of several metres, and to bear as many as 300 flowers, which are white, with a purple disc to the sepals and petals, and a violet-purple lip. It is dedicated to His Majesty, Leopold II., King of the Belgians.—*Gardeners' Chronicle*, November 15th, p. 556.

CATTLEYA O'BRIENIANA.—A plant of this was exhibited at a meeting of the Royal Horticultural Society on November 11th last by Messrs. F. Sander & Co., of St. Albans. It is said to have light purple sepals and petals and a lip with crimson splashing. From a flower which I have seen I suspect it to be a pale form of *C. Harrisoniae*.—*Gardeners' Chronicle*, November 15th, p. 556.

ODONTOGLOSSUM DAVIVIERIANUM, Rchb. f.—A supposed natural hybrid between *O. maculatum* and *O. nebulosum*. It was exhibited by Messrs. Linden, L'Horticulture Internationale, Brussels, at a meeting of the Royal Horticultural Society on November 11th last, when it received an award of merit.—*Gardeners' Chronicle*, November 15th, p. 570, and 22d, p. 602.

ODONTOGLOSSUM NOEZLIANUM.—"A dwarf, delicate-growing novelty, with small, circular, bright scarlet flowers." It was exhibited by Messrs. Linden, L'Horticulture Internationale, Brussels, at a meeting of the Royal Horticultural Society on November 11th last, when it was awarded a botanical certificate. I have not seen it.—*Gardeners' Chronicle*, November 15th, p. 570, and 22d, p. 602.

SOPHRO-CATTLEYA X *CALYPSO*, Rolfe, is a beautiful hybrid raised by Mr. Seden for Messrs. James Veitch & Sons, of Chelsea, from *Sophronitis grandiflora*, fertilized with the pollen of *Cattleya Loddigesii*, var. *Harrisoniae*. The sepals and petals are of a brilliant rose-purple, much like those of the *Sophronitis* in shape, while the lip, which much resembles the pollen parent in shape, is light yellow, passing into pink on the margin of the side lobes, and into deep yellow on the base of the front lobe, the apical half of which is crimson-purple.—*Gardeners' Chronicle*, November 22d, p. 588.

Cultural Department.

A Winter Lettuce Crop.

THE accompanying illustration, taken from a photograph, shows a section of a crop of Lettuce which is now (December 8th) maturing in the forcing-houses of the Cornell Experiment Station. It was grown primarily to be used for one of a series of experiments to determine the influence of the electric light upon various plants. Owing to a delay in establishing the light, no study of this kind will be made until the succeeding crop, but it still serves admirably to illustrate a successful method of culture.

The crop is a remarkably even one, not a single plant being missing from the bed, which is sixty feet long. There are two varieties shown in the picture, the plants upon the right half being the Tennis Ball or Boston Market, and those upon the left Landreth's Forcing Lettuce. In this crop the latter variety has surpassed even the old and popular Tennis Ball, while growing side by side with it and under precisely the same conditions, the heads being somewhat darker in color, and uniformly larger and heavier.

The seed was sown about the 1st of October in shallow seed-boxes or "flats," and transplanted two weeks later ten by twelve inches apart into the soil upon the benches. As with other forcing crops, the arrangement of the beds is a matter of considerable importance. In this house, constructed for various experiment purposes, the steam pipes are beneath the benches, an arrangement which is not essential for a Lettuce-crop, and in order to moderate the bottom heat the benches were double-boarded. To provide for drainage a layer of clinkers from the ash-pit was first placed over the boarding about an inch in depth. This was succeeded by three inches of roughly broken compost, consisting of two-thirds partially decayed sods and one-third stable manure, the whole being then covered by three inches of mellow garden soil, thus making a total depth of seven or eight inches upon the benches. With such a body of soil the conditions as regards moisture may be made approximately the same as those of out-door culture. If the soil is much shallower than this, it is constantly liable to become dried out as well as too warm, with a consequent check to the growth of the plants.

In forcing Lettuce it must be borne in mind that it is a comparatively hardy plant, which thrives best in a temperature which would be far too low for most of our forcing crops. In this case the effort has been to maintain a temperature at night of fifty degrees, and by day of ten to fifteen degrees higher. Of the two chief hindrances in the forcing of Lettuce, mildew and the aphid, the former has not made its appearance, and the

latter has been held in check by frequently burning tobacco-stems, lately as often as two or three times a week.

About two weeks before the maturing of the crop provision was made for a succeeding crop by again sowing seed in the flats, and as soon as the beds are cleared the space will be at once filled by the seedlings now growing for that purpose. When every day's growth of a crop is made at the expense of burning many pounds of coal, it is manifestly of the highest importance that the crop should be pushed to maturity as rapidly as possible and the strictest economy of time and space be studied in providing for their succession.

Cornell University.

C. W. Mathews.

Begonias.

THE cultivation of Begonias would seem to be a trite subject, but one finds among friends but limited collections of these desirable plants, and perhaps a few notes of interesting varieties may prove helpful to novices. There are said to be over 300 species of Begonias, and, of course, hybrids innumerable. With their widely divergent forms and habits, they are of great interest, and one could busy himself at all seasons collecting and cultivating this genus alone. Few plants of such easy culture are so satisfactory in bloom and so readily grown into specimens, and there is a constant change of interest as the various sections come into season. During the winter the greenhouse may be kept gay with handsome foliage and graceful flowers of many herbaceous kinds, of *B. Socotrana* and of hybrids of the tuberous section. In early spring the various tuberous species and hybrids will commence to move and make ready to replace the winter bloomers, which may be plunged in the borders to regain vigorous health. One pleasing point about most herbaceous kinds, which small growers will appreciate, is that such plants as one may have no room to cultivate may be kept nearly dormant at any time by cutting them down and keeping them nearly dry and pot-bound. For the greenhouse and conservatory decoration, fancy-leaved kinds will be found desirable, a few of the Rex varieties possibly, and those of distinct and striking form and leaf structure. Perhaps the most useful of fancy-leaved Begonias is the well known *B. metallica*, as this not only forms a handsome plant, but furnishes a larger supply of foliage suitable for cutting than perhaps any other variety. Clementina, a hybrid between a form of *B. Rex* and *Diadema*, is an excellent new variety, with characteristics of both parents, a handsome and vigorous grower. *Diadema* and *Sceptrum* are two attractive varieties, with rather palmate-like, deeply cut leaves and silver markings.

B. Verschaffeltii, *B. ricinifolia maculata* and *B. Sunderbruchii* are three forms with large, deeply cut leaves on long foot-stalks, which are distinct and effective for decoration. They bloom in summer. *B. rubella* is also a distinct and desirable kind of similar habits. Its large, bronzy red leaves are thickly dotted with black spots.

B. Scharffiana, a new species, is a beautiful plant with large massive leaves on thick, fleshy red stems. The leaves are bright emerald green on the upper and deep red on the under side. The whole plant is covered profusely with short hairs. One feature of this plant is the refined beauty of the young leaves as they push out from the delicate greenish white scapes in which they are first enveloped. My plants, though large and nearly two feet high, have not yet bloomed. They are said to have good-sized white flowers, but these can scarcely add to the ornamental character of this species. Of varieties with fine flowers and handsome foliage *Gloire de Sceaux* may have first mention—a vigorous variety with leaves of polished bronze and large racemes of rose colored flowers. *Gloire de Jony* and *Madame Hardy* are two fine hybrids of *B. subpeltata*, with large pink flowers and beautiful foliage, the former light olive green and with a metallic sheen dotted with silver, the latter dark wine colored, checkered and covered with a crimson pile. *B. Olbia* is a species which is indispensable, though the beautiful crystalline flowers are axillary and not prominent. Its delicate, finely veined leaves are deeply cut, a dull red beneath, and of an indescribable combination of metallic bronzy green and red above. The entire effect of this plant with its beautiful foliage and its white, thick, tapering stems is very distinct and pleasing.

Of the varieties chiefly valuable for their flowers, though more or less ornamental, perhaps the first place should be given to *B. Socotrana*, which is proving such a valuable plant to the hybridizer. This variety starts into growth in September from bulblets formed at the base of the old plant. Its leaves are deep green, round, depressed in the centre and recurved at the margin; the flowers are bright rose, one and a half to two inches across, and last for a long time. From this species we

now have a few winter-blooming tuberous kinds with showy flowers. John Heal and Adonis are the best known of these. The former is said not to be a good grower. Triomphe de Lemoine is a hybrid from *B. Socotrana* and is a vigorous variety. This has already been figured in GARDEN AND FOREST. *B. Socotrana* has also given a hybrid with *B. insignis* named Bijou, which I find is a satisfactory kind with twiggy stems, prostrate habit and bright magenta flowers. *B. incarnata* is an established favorite among the winter-flowering kinds, and the French have given us a few varieties of this varying in color of flowers. Of these M. Crousse, M. Choner, M. Ed. Pynaert and M. Vallerand are the best.

The Semperflorens type are perhaps the most useful Begonias for flowers, being, as implied by name, very free bloomers. The varieties of this are very numerous, and the flowers range in color from white, through pink to deepest carmine. Some of the most useful varieties are Elegans, Bruanti, Lucianæ and Bajocensis.

A strain with more vigorous, taller habit and larger leaves is *B. semperflorens gigantea*, very useful for back rows and producing large racemes of fair sized flowers. The best of these are Odorata (Dr. Nachtigal), Amelia, Rosea and Carminea.

that a wider distribution of some of the kinds noted above would increase the interest of many growers whose attention had not been called to them.

Elizabeth, N. J.

J. N. Gerard.

Filmy Ferns.

THE exceptional interest and charm of the Filmy Ferns, both as objects of study and as ornamental plants, is generally recognized. Botanically they have always received considerable attention on account of their special structure, which differs so markedly from that of the rest of the Ferns that some authors have separated them into a sub-order. Their vegetative peculiarities are being specially studied by more than one botanist in England at the present time. Horticulturists are attracted to them by the elegance and delicacy of their fronds, and their cultivation is a special hobby with several amateurs, while a few of the species, such as *Todea superba* and the Killarney Fern (*Trichomanes radicans*), are grown among Ferns generally. There are, however, a considerable number of beautiful species, known to and cultivated by a few specialists, which are quite as easy to manage as those already named, and, in fact, may be grown under precisely similar conditions

Lettuce in a Forcing-house.—See page 622.

Among the more striking of newer Begonias Paul Bruant is probably the best. A vigorous variety, with deep cut light olive leaves, with toothed edges and bearing a great profusion of light rose flowers in racemes. M. de Lesseps is in the way of *Argentea guttata* with larger, darker leaves. Of older varieties, Mr. Barker has already called attention in GARDEN AND FOREST to *B. manicata* and *B. manicata aurea* (the variegated variety), very useful kinds, which in mid-winter fairly burst into blossom with numerous racemes of small pink flowers. *B. Gibsoni*, of course, must be noted as quite indispensable with its rosy blooms partly doubled, and among a host of older favorites are *Compta*, with pink stems, satiny green leaves and a silvery tinge along the mid-rib; *Decora*, with dark green silver-marked leaves; *Argentea guttata*, which some one has called Angels' Wings; and its wing-like silver dotted leaves bear out the name very well. But space forbids even naming many established favorites whose various charms and strange forms make these plants so interesting. Among the varieties one may find kinds simulating in foliage other plants of widely divergent habits, and even an annual species, *B. Schmidtii*, self-sown seedlings of which are continually appearing in all available spaces. Their habits are nearly as diverse as their foliage. Among them are dwarfs and giants, plants stiffly upright and scandent, and all intermediate forms with strongly marked periods of growth and rest in many cases.

Every one who cultivates flowers has a few much appreciated Begonias and they are no novelties; but it would seem

with the Killarney Fern and the New Zealand Todeas. It is probable that many have avoided Filmy Ferns from a belief that they could only be grown where conditions of a very special character were provided. This belief is supported by the miserable health of Filmy Ferns in many gardens where their cultivation is attempted. Failure in these cases is, as a rule, obviously the result of ignorance of two very simple, but vital, factors in the healthy growth of these plants—namely, moisture and ample drainage. Filmy Ferns detest lime; they should, therefore, be watered with rain-water. As a rule, they dislike watering overhead, although the atmosphere about them should be kept constantly saturated. They will not thrive if planted in heavy or close soil. Peat fibre and pieces of soft sandstone, or even a bare piece of sandstone alone, or a piece of soft Fern-stem, afford the most suitable material for their roots and creeping rhizomes to cling to. If they are to be grown in pots and covered with bell-glasses, then the whole of the pot should be filled with drainage, upon which a little mound may be built with peat-fibre and sandstone. The plants should then be fastened onto this by means of wooden, not wire, pegs. To water plants thus treated, dipping the pot up to the rim in water or pouring water over the bell-glass so that it will run down into the pot, answers very well. If a frame can be afforded for Filmy Ferns alone the preparation in regard to drainage and soil should be similar to that recommended for pots. The surface of the soil may be varied by raising some parts higher than others by the free use of sand-

stone. In watering the frame do not use a rose-nozzle, but pour the water from the spout of the can onto the stones or anywhere except on the leaves of the Ferns.

All Filmy Ferns require a subdued light at all times of the year. In a state of nature they are found only in very sheltered spots, often clothing the under surface of stones or fallen tree-trunks, always in positions protected from wind and the drying influence of sunshine. If the sun is allowed to shine direct upon them only for an hour or so in summer they become dried and shriveled beyond recovery. Some of the species, particularly *Todeas*, may be grown in positions where they would get a moderate amount of sunshine, but fine specimens cannot be produced by its means.

The temperature most congenial to Filmy Ferns when under cultivation has only recently been arrived at. A few years ago the general belief with regard to all Filmy Ferns except the *Todeas*, the Killarney Fern and New Zealand species was that they required a tropical temperature. The discovery that this was an error was purely accidental. The late Dr. Cooper Forster, who had grown a large collection of Filmy Ferns in a conservatory attached to his surgery in Grosvenor Street, related how, on his heating apparatus breaking down, he was forced to leave his plants to their fate. Instead of dying from the reduced temperature, as he expected, the majority of them displayed a vigor of growth and depth of color which told their own story unmistakably. Even pteridologists were incredulous of this story until they saw its proof in the health of the collection of plants in Grosvenor Street. It was plain enough that many of the species which hailed from distinctly tropical regions were much happier when under cultivation in England if the temperature for them was kept comparatively low. At the time of Dr. Cooper Forster's discovery the Kew collection was grown in a temperature which in winter never sank below sixty degrees nor in summer below seventy degrees. With the exception of a few species, which were either too precious to risk in an experiment or were perfectly happy in a stove temperature, the whole collection was removed to a cool fernery in 1885. In this house no fire heat is used except during winter, in frosty weather the thermometer often registering fifty degrees or even forty-five degrees. With scarcely an exception the whole of the plants have proved not only able to support this low temperature, but the growth has been uniformly better than it was when they were in a warmer place. Many of them are from tropical regions where it is scarcely likely that they would ever experience a temperature anything like as low as they enjoy when under artificial cultivation. The following list comprises all the species which thrive in the cool fernery at Kew:

<i>Hymenophyllum æruginosum.</i>	<i>Trichomanes alatum.</i>
" <i>asplenoides.</i>	" <i>var. attenuatum.</i>
" <i>axillare.</i>	" <i>apiculatum.</i>
" <i>caudiculatum.</i>	" <i>auriculatum.</i>
" <i>chilense.</i>	" <i>Colensoi.</i>
" <i>ciliatum.</i>	" <i>crinitum.</i>
" <i>cruentum.</i>	" <i>depauperatum.</i>
" <i>demissum.</i>	" <i>digitatum.</i>
" <i>var. minus.</i>	" <i>exsectum.</i>
" <i>var. nitens.</i>	" <i>Filicula.</i>
" <i>dichotomum.</i>	" <i>feniculaceum.</i>
" <i>dilatatum.</i>	" <i>humile.</i>
" <i>flabellatum.</i>	" <i>lucens.</i>
" <i>Fosterianum.</i>	" <i>maximum.</i>
" <i>fuciforme.</i>	" <i>membranaceum.</i>
" <i>hirsutum.</i>	" <i>parvulum.</i>
" <i>Javanicum.</i>	" <i>pusillum.</i>
" <i>var. cristatum.</i>	" <i>pyxidiferum.</i>
" <i>var. flexuosum.</i>	" <i>var. olivaceum.</i>
" <i>lineare.</i>	" <i>radicans.</i>
" <i>Lyallii.</i>	" <i>var. Andrewsii.</i>
" <i>multifidum.</i>	" <i>var. Boschianum.</i>
" <i>obtusatum.</i>	" <i>var. concinnum.</i>
" <i>pectinatum.</i>	" <i>var. dilatatum.</i>
" <i>var. superbum.</i>	" <i>var. dissectum.</i>
" <i>polyanthos.</i>	" <i>var. Luschnati-</i>
" <i>pulcherrimum.</i>	<i>anum prolongum.</i>
" <i>rarum.</i>	<i>Trichomanes radicans, var. Lusch-</i>
" <i>scabrum.</i>	<i>natianum pulchrum.</i>
" <i>sericeum.</i>	<i>Trichomanes radicans, var. Lusch-</i>
" <i>tamaricifolium.</i>	<i>natianum superbum.</i>
" <i>Tumbridgense.</i>	<i>Trichomanes reniforme.</i>
" <i>var. Wilsoni.</i>	" <i>rigidum.</i>
" <i>valvatum.</i>	" <i>var. elongatum.</i>
<i>Todea Fraseri.</i>	" <i>sinuosum.</i>
" <i>var. Wilkesiana.</i>	" <i>strictum.</i>
" <i>grandipinnula.</i>	" <i>tenerum.</i>
" <i>hymenophylloides.</i>	" <i>trichodeum.</i>
" <i>plumosa.</i>	" <i>venosum.</i>
" <i>superba.</i>	

W. Watson.

Ruellia macrantha is certainly one of the most ornamental of the many cultivated winter flowering Acanthads, but it is scarcely known in gardens. It is a native of Brazil, from whence it was introduced by Van Houtte in 1875 and figured in the *Revue Horticole* the year following. It forms a compact many stemmed shrub from a foot to two feet in height, with oblong-lanceolate bright green leaves six inches long. The flowers are produced singly in the axils of the upper leaves, and as many as six flowers are opened together on each shoot. The calyx is formed of five linear segments an inch long, and is subtended by a pair of oblong green bracts also an inch in length. The corolla at the base is in the form of a narrow tube about an inch long, then broadly campanulate with five ovate spreading segments. The length of the whole flower is three inches and it measures three inches across the top. The color is a rich purplish rose, very similar to that of *Bougainvillea spectabilis*. The flowers last at least a week when cut and placed in water. The plant is easily propagated by means of cuttings, and it grows freely in an ordinary stove. Other species of *Ruellia* which are useful as winter-flowering plants are *R. Herbstii*, with terminal clusters of tubular flowers colored magenta and lilac; *R. macrophylla*, with brilliant scarlet *Salvia*-like flowers; *R. affinis*, with an erect semi-scandent habit, large, dark green leaves and terminal clusters of salmon red flowers almost as large as those of *R. macrantha*. These plants formerly belonged to the genus *Dipteracanthus*, now merged in *Ruellia*. *R. macrantha* can be recommended as an exceptionally good stove-flowering plant.

Iris stylosa is a useful plant as a source of cut flowers in early winter. It is generally considered a shy bloomer, but when planted close against the south wall of a greenhouse it blooms profusely from October into December. At any rate, some plants obtained last year from a French nurseryman and planted in the same border with the *Jacobæa Lily* (*Sprekelia*) have been flowering freely since October, and are bearing good flowers now, notwithstanding the severe frost and snow of the past fortnight. *I. stylosa* is a native of Algeria, where it is common in the hedges. It has a creeping rhizome, evergreen narrow leaves, one and a half feet long; scapes about a foot long, one-flowered; each flower is nearly three inches across and colored a rich purple-blue, with a few lines of yellow on the falls. It has been in cultivation over twenty years. There are several named varieties of it, one with white flowers. It is described as a spring-flowering species.

Kew.

B.

Clematis Stans.—This plant when in growth and covered with foliage would appear to belong to the same section as *C. Davidiana* and *C. tubulosa*, and has in fact been described as a white *C. Davidiana*. All three of the above plants resemble each other in having leaves like the Japan Anemones, but the likeness ends here. *C. tubulosa* has deep blue flowers, and *C. Davidiana* light lavender blue, both being hardy herbaceous plants, while *C. Stans* has white flowers and is a hardy shrub. This statement is made because *C. Stans* is often called a hardy perennial, which it is, but not a herbaceous perennial, as many are led to suppose. The plant grows three or four feet high, the main stems being woody, and they bear close resemblance to the wood of a Grapevine, being of the same color and thickness, while the leaves are always opposite, with plump buds at their base. The propagation of this *Clematis* is easily effected by means of the hard wood and the axillary buds. The shoots may be cut up into single eyes, as is done with the Grapevine, and when placed in sand in a propagating bench they will make callus and grow readily. Apart from the beauty of this plant, *C. Stans* is the best species from which to obtain roots upon which to graft other species of *Clematis*. It is well known that *Clematis* come slowly from seed, and consequently grafting is resorted to as a much quicker method of reproduction. We have tried the roots of several species, but none united so readily with the cion as those of *C. Stans*. The union was perfect in two weeks, and the ligature could be removed with perfect safety. This species has therefore a peculiar value not only as a decorative plant, and on account of the ease with which it may be increased, but because it is such a help in multiplying other species and varieties which without such a convenient stock increase but slowly.

South Lancaster, Mass.

E. O. Orpet.

Dianthus plumarius semperflorens.—With regard to the origin of this plant, to which allusion has already been made on page 562 of this volume, Mr. Thompson, of Ipswich, England, writes that M. Alphonse Alégatière, of Lyons, France, obtained it by crossing the best forms of the florists' Pink (*D. plumarius*) with a Perpetual Carnation. He adds that the first lot of seed he obtained and distributed was the only one of any value,

subsequent supplies turning out to be ordinary Carnations of no value whatever. It will, perhaps, be remembered that Monsieur Aléatière was the originator of that excellent class of Tree or Perpetual Carnations, well represented by such varieties as A. Aléatière, Cardinal, Miss Joliffe and Souvenir de la Malmaison, which was so much improved by the late Mr. Charles Turner, of Slough, England.

The Forest.

Value of Mountain Forests.—II.

ANOTHER important function of mountain forests is the production and maintenance of such conditions of the soil, water, atmosphere and scenery of the region as are highly favorable to human life, health and enjoyment. An evergreen mountain forest like that of our White Mountain region is a great natural sanitarium, one of the best and most effective in the world in its life-giving and health-restoring qualities. The destruction of forest-conditions over this region would distinctly shorten the lives of great numbers of persons. It would be a serious error to conclude that the sanitary influences of these mountain forests are important only or chiefly to persons already affected by disease. The millions of dwellers in cities all need a season of out-of-door rest and recreation in summer in order to maintain the physical and mental health and soundness which are essential to success in the work of life. Our New Hampshire mountain forest-region is a summer playground for the inhabitants of Boston, New York, Philadelphia and the great cities of the south and west. As their population increases our entire area of forests, lakes and streams will be needed for this purpose, and it will soon all be brought into use if its attractiveness is not destroyed by despoiling the woods and waters of their freshness and beauty. For the weariness and exhaustion of vitality which so often result from excessive activity in the crowded life of towns and cities there is no healing influence more effective than the silent unconcern of Nature amid the scenes and conditions of summer residence in a mountain forest-region.

FISH AND GAME PRESERVES.

As a part of this sanitary function of mountain forests, their value as natural preserves for fish and game deserves far more serious and intelligent attention than it generally receives. Some occupation is necessary for many persons who go to the woods for summer rest and recreation, and the pursuit of game and fish supplies both physical and mental conditions which are highly favorable and restorative. The slaughter of game of any kind for the mere sake of killing, and of delight in the quantity butchered, is not only unsportsmanlike; it is coarse and disgraceful, and should receive pronounced disapproval everywhere. But fishing and hunting, as pursued by civilized and orderly anglers and hunters, are legitimate and proper means of recreation. If the forests are destroyed there will soon be neither fish nor game. When the shaded brooks are opened to the sun the trout will disappear, and when the wilds are despoiled of their sylvan beauty and sheltered solitudes the hunter's delight in them will be at an end.

The value of mountain forests on account of the beauty and charm of their scenery is closely allied to the sanitary influences already mentioned, and beauty of scenery—in addition to its power to produce happiness, to awaken and nourish "vital feelings of delight," and because of this power—beauty of scenery has in modern times great economic value. Switzerland and Norway and other mountainous countries in Europe derive important revenues from their scenery, which attracts multitudes of visitors from all parts of the civilized world. New Hampshire is remarkable for having so much attractive scenery, so many beautiful landscapes distinct from each other, within a comparatively small area of country. In this respect it is unequaled in any part of the United States. Several millions of dollars are brought to the hands of our people every year by summer tourists and boarders, and yet the attractions of our mountain region are by no means fully developed. But these valuable revenues will be diverted to other parts of our country, and to Europe, unless our mountain forests and streams are protected and preserved.

THE UPPER COÖS COUNTRY.

The fertile valley land of the upper Connecticut River is now at its best. The hills on each side were, until a few years ago, heavily covered with valuable timber. Now they have all been lumbered over. This would not of itself do any harm. Timber should always be cut when it reaches its best condition. That is what it is for. But at many points in this Upper

Coös country the steep slopes rising from the valley on each side have been burned over till the root-mat which held the soil in place is breaking up. The young people of our day are likely to live to see this rich upper Connecticut valley almost completely destroyed. The surface materials of the hills will be carried down more and more by the action of the water in the spring season, and will bury the soil of the valley under deposits of inert substances. There are already places on these slopes where trees will never grow again.

Both Connecticut Lake and Second Lake were formerly surrounded by woods, and the trees grew to the very edge of the water. In order to land, when rowing, a man had to push his boat up among the boughs of the trees and climb out on them, unless there was a landing cleared by the axe. The blue sky never bent over anything in Nature more beautiful than these mountain lakes of crystal clearness, with their miles of shoreline one continuous fringe and wall of green foliage. But Connecticut Lake has been dammed to raise the water to float logs. The back-water has killed the timber, and now all the lower portions of the shores are ghastly and repulsive tracts where the decaying tree-trunks are gradually dropping into the polluted water below. This destruction of the timber by the back-water was entirely unnecessary.

All the country around Connecticut Lake and Second Lake and between the two, and part of the way from Second to Third Lake, has been lumbered over. The timber is not all removed, and from a distance the forest still looks green, but in the woods the tangled mass of fallen trees and tree-tops is almost impassable.

The wilderness around Third Lake has not yet been disturbed. This lovely sheet of water is in the heart of a primeval and not easily penetrable forest, and the traveler is here companioned by the sources of the Connecticut River. The lake extends within a mile or so of the Canadian line. In the upper Connecticut valley men feel as if the world had just been made and given to them. They say, "Why, there's hardly anything *but* woods! We haven't begun on them yet." It seems to them as if the forests around them were inexhaustible, but the price of timber lands is advancing in every part of our country because business men have become aware that the White Pine supply of the upper Mississippi Valley is speedily coming to an end, and that everywhere our consumption of timber greatly exceeds the rate of growth. People are unwilling to think of the future, to recognize the conditions which will surround their children. Yet without such foresight the permanence of what we value most in our civilization is impossible.—From the Report of J. B. Harrison, Commissioner of Forests for New Hampshire.

Correspondence.

The English Sparrow.

To the Editor of GARDEN AND FOREST:

Sir.—I have read lately in the Journal of the French Société d'Acclimatation an account of the damage done in the United States by the English sparrow. It was a most unfortunate idea introducing into America these birds, always more destructive than useful, without introducing, too, their natural enemy, created, apparently, expressly to check their excessive multiplication. This enemy of the European sparrow, which it certainly would not be difficult to naturalize in the United States, is the pigmy owl known in France under the name of Chevéche, the *Stryx passerina* of Linnæus. He is a ferocious and well-armed bird, able from his small size to enter into small holes in walls or rotten trees, or wherever the sparrows make their nests. Although the Chevéche attacks rats and mice like the other species of Stryx, his specialty as a carnivorous bird is to destroy sparrows. He is not larger than a blackbird, although shorter and stouter. The short, strongly-armed claws of this bird permit him to climb up the face of a wall and to ascend and descend the cavities of old trees, into which he plunges without hesitation. This little bird inhabits, too, churches and all sorts of old buildings, and, in a word, all the out-of-the-way places which the other birds of the same genus seek. He is only partly nocturnal, beginning to hunt his prey at dusk. The Chevéche not only exterminates the sparrows' nests, but it drives them away entirely by its presence alone from any locality. Sparrows so fear this bird that whole flocks of them depart as soon as they notice that it is established in any particular region. This little owl to the sparrow is like the presence of a wolf in a sheep-fold.

It seems to me, therefore, that it would be an interesting experiment to try to naturalize this bird in America. In order to make the attempt successful, and this is true in all efforts to naturalize birds, there are certain conditions which must be

fulfilled; the most important is to procure for the strangers houses and retreats where they can find shelter and can rear their young in safety. Numerous laws have been adopted in France for the protection of insectivorous birds, although none of them have yet produced any very satisfactory results. And this must always be the case as long as people cannot be made to understand that birds need places of refuge in which to build their nests and breed without fear of being disturbed by man, or by dogs, cats and other destructive animals.

The stupid destruction of nocturnal carnivorous animals, like owls, bats, etc., is one of the great agricultural errors of our time, and it is safe to say that the enormous losses in crops due to rats, mice and various insects are largely in consequence of this error. Rabbits in Australia are ruining crops, and still they might be got rid of by introducing the great owl (*Stryx bubo*), the special enemy of rabbits, and other large carnivorous animals like eagles, which are not rare in the south of France. It is certainly astonishing in this era of progress that the world does not know better how to make use of such assistance as nature offers us free of charge.

Villa Thuret, Antibes.

Charles Naudin.

Why Private Grounds Should be Enclosed.

To the Editor of GARDEN AND FOREST:

Sir.—The article on "Private Grounds in Cities and Towns" in your issue of December 10th prompts me to make a plea for enclosures, for the appearance of privacy in the grounds about a house, as the matter is in my mind every day as I look about my own neighborhood. I am glad that Mr. Baxter admits the "great charm in a 'close,'" but I regret that he treats it as almost an impossibility in this age and country, and wholly at variance with our habits and character, something to be relinquished with a sigh rather than to be sought and striven for.

I know nothing of landscape-gardening, and speak merely as a suburban dweller, accustomed to see his own small grounds and those of his friends from within and to look on the property of others from without, and to feel that from whichever point the usual surroundings of an American suburban house are looked at, their attraction depends chiefly on the extent to which they give an impression of privacy. It is true that a low, open fence of rails or palings gives little privacy, and, unless covered with vines, may be unsightly; but thick, high, graceful hedges, while grown less easily than in Europe, are possible with care, and should by all means be encouraged. A private lawn, be it large or small, with nothing to separate it from the public street, looks, to me, undressed and undignified.

Why is not the desire for privacy thoroughly healthy and sensible? So long as a man surrounds his property with nothing unsightly, his duty to the public is done. He cannot be called upon to share his grounds with them. We attach a great deal of importance to the idea of home, priding ourselves upon the home-loving spirit as something peculiar to our race. Who could take pleasure in a home with no front walls to the rooms, or with those walls of glass so that every passer-by could see all that was going on?—and yet why should the house alone be home, why should not the home idea include the grass and trees and flowers about a house?

Then, too, barriers, as was said in GARDEN AND FOREST last year (vol. ii., p. 193), give "the element of mystery, of surprise and expectancy, the impression and promise of something still before us and beyond what we can see, which may minister a fresh delight." Why should the public be refused the pleasures of imagination as to what may lie behind the hedge, and be given only the cold, hard facts of a small grass plat and a few regulation dwarf trees and stiff flower-beds?

I believe that the first step of most village improvement societies is to seek to remove whatever separates private grounds from the street. By this they cut at the root of that public spirit and that love of the picturesque which they seek to gratify and develop. No man will care much to make the village attractive who does not care to make his own grounds so; and how much is he likely to care about them when he regards them not as part of his own home, but merely as an adjunct to the street? Again, the desire to see into a neighbor's grounds, to enjoy his property without cost, regardless of how much his own use of it may be abridged thereby, is the very opposite of public spirit. These societies may do well to attack unsightly fences; but they should recommend something better in their place, and remember that the love of due privacy is not to be condemned, for it is generally found closely allied to the love of the beautiful and the love of nature.

Mount Airy, Philadelphia.

Charles C. Binney.

Autumn Colors in Oregon.

To the Editor of GARDEN AND FOREST:

Sir.—In a contribution to GARDEN AND FOREST last year concerning the autumnal coloring of this region I failed to mention one of the most interesting plants of our western flora, the Azalea of the Pacific coast, *Rhododendron occidentale*, known here almost universally as the "Honeysuckle." This popular name has descended to it, doubtless, from its eastern cousins, *R. viscosum* and *R. nudiflorum*, which are commonly called by this name. It is a handsome shrub, quite abundant in many wooded districts. In others it is seen only now and then near the borders of streams, or sometimes forming handsome clumps in some neglected corner of the field. But, wherever seen, in the fall of the year its leaves glow with such a profusion of scarlet and crimson mingled with the gold and green, that it produces the most delightful effects, which are none the less pleasing, it seems to me, than those it produces when in full flower.

Prunus subcordata, the wild Plum of this region, should also have been mentioned. The wild Plum sometimes becomes a small tree, but is seen generally as a small shrub three to four or five feet in height. It often sets the whole countryside ablaze in the autumn with the abundance of its scarlet and crimson colors, mingled, of course, with red and yellow, and garnished with a sprinkling of green.

Just at this time (November 27th), however, most of our deciduous trees and shrubs are stripped of their foliage, only a few of the Cottonwoods and Alders, and sometimes the sprouts about the base of a felled Oak, still holding a portion of their leaves. But the Willows have been conspicuous for the past week or two by the bright yellow of their leaves. These flame out into the brightest of yellow colors just as the deeper and richer scarlets and crimsons and reds are about dying out. The Willows here rarely form trees, but grow mostly in great clusters of slender, wand-like stems, the younger sprouts being very handsome in the winter with the polished green and red of their bark.

But in the cultivated orchards many of the Pear, Peach and Apple-trees still hold their leaves. The Prunes and Plums and Cherries, however, are bare. I notice that the Periwinkle (*Vinca*), which our people here almost universally call "Myrtle," and a few other garden plants, are yet in bloom, with expanding flower-buds on late blooming Roses.

Wimer, Ore.

E. W. Hammond.

Planting a Screen.

To the Editor of GARDEN AND FOREST:

Sir.—I have been wishing to plant as a screen and for variety some Staghorn and Glabrous Sumachs, and have hunted for suggestions as to the best method of transplanting to secure the best and speediest results. In early November I selected the best specimens I could find on the road-side and put them in rather poor and shallow soil. The specimens I selected were as tall as any I remember to have seen, the Staghorn certainly eight feet high, the other, I should think, four to five feet high. Then I had a thick mulch of coarse manure applied, and in December I contemplate cutting them down about one-third. Can you suggest any treatment better than this?

Wm. A. Jenner.

[The mulching and cutting back are good treatment. Perhaps smaller plants would have been preferable.—Ed.]

Sporting of Chrysanthemums.

To the Editor of GARDEN AND FOREST:

Sir.—The variable coloring of Chrysanthemums forms an interesting subject for speculation and research, and can hardly be studied too minutely. At least one or two features of this tendency to sport I have not seen mentioned in print. Several years ago I bought a single plant of Fair Maid of Guernsey, a white variety with almost globe-shaped flowers and finely quilled petals. Next season I raised several plants from the original one, and was surprised to notice that while some of them flowered after the fashion of the old stock, others produced a flat flower, with petals as broad and open as Elaine or Puritan. At that time I had but the single variety, and there were no other Chrysanthemum cultivators in the vicinity. The sporting apparently all occurred in one season, and the variation appears to remain true, though of that I cannot speak positively. The original plant from which all the others came is still in existence and has not changed its appearance. I have now marked several specimens of both forms and shall watch them carefully.

Two plants of the flat petaled form were left outside this fall till late in November, and both developed a rich purplish tinge on the lower side of the outer petals that was quite striking. From this fact and from the fact that Duchess, one of the most variable in coloring, is usually almost white when subjected to undue cold, it would appear that the state of the atmosphere has much to do with sporting. Duchess is also easily affected by poor light, becoming faint yellow instead of its usual "Zinnia red" color. It will doubtless be found that heat and light are together accountable for about all there is of the change of color in Chrysanthemums. But this does not explain the opening out of the petals of the Fair Maid of Guernsey.

Buffalo, N. Y.

Recent Publications.

The Forests of North America.—III.

Die Waldungen von Nordamerika ihre Holzarten, etc.

In the previous notices of this work (pp. 193, 200) special attention was given to that part of Dr. Mayr's work relating to the distribution of forests and the species of trees of which they are composed. There now remains another portion of the work to notice—that devoted to Fungus parasites. This part of Dr. Mayr's work, although it occupies but a comparatively small fraction of the whole, contains a number of errors and inaccuracies of statement which should hardly be allowed to pass without criticism. On pages 433, 434, the author enumerates thirty-four species of Fungus parasites, including two new genera and thirteen new species, although he expresses a doubt with regard to three of the latter. Besides the list to which we have referred there are notes and descriptions of some of the species of fungi scattered through the text.

If there is any genus of fungi found in the United States whose development has been more frequently and carefully studied than any other, it is probably the genus *Gymnosporangium*, and there seems no good reason why a foreigner writing on our fungi should not first read what has already been published in America as well as in Europe. Dr. Mayr cites *Roestelia lacerata*, Sow, on *Cratægus* as connected with *Gymnosporangium macrocarpum* on *Juniperus Virginiana*. But it is a well known fact, as shown by the cultures of Thaxter and confirmed by others, that the *Roestelia* in this case is not *R. lacerata*, Sow, but *R. pyrata* (Schw.) The name of the *Gymnosporangium*, moreover, is not *G. macrocarpum*, but *G. macrospus*, Lk., first described by Schweinitz in 1822 under the name of *G. Juniperi Virginiana*. The spelling cannot be considered a printer's error, for it is given as *macrocarpum* in the list and again incorrectly as *macrosporum* on page 195 and in the index. The author evidently has not studied with care the *Gymnosporangia* which abound in the United States, for on page 195, in speaking of *Juniperus Virginiana*, he says "Except *G. macrosporum*, which causes a witchesbroom distortion (Hexenbesen), the tree seems to have no enemies." The statement is incorrect in two ways. The witchesbroom distortion is not caused by *G. macrospus*, which produces the familiar "Cedar-apple," but by a different species. Furthermore, *J. Virginiana*, far from having no enemies, is peculiarly susceptible to the attacks of fungi, and, of the genus *Gymnosporangium* alone, *G. macrospus*, *G. globosum*, *G. clavipes* and one other species are common on that host.

The author records on leaves and shoots of *Fraxinus* an *Æcidium*, the species of which he considers to be in doubt. But why should there be any doubt? The species is one of the best known and most striking in appearance—*Æc. Fraxini*, described by Schweinitz in 1822. On the other hand, with regard to the new species which he calls *Rhytisma punctiforme*, the author has apparently no doubt; but, unfortunately, Dr. Mayr was anticipated by Fries, who described the fungus under the name of *R. punctatum* more than fifty years ago. There is cited on *Cornus florida* a *Microsphaera* (*Erysiphe*) *Corni*, n. sp., which is also figured under the name of *Podosphæra Corni*. As the figure apparently represents more than one ascus in a perithecium, the name *Podosphæra* was probably a slip of the pen; but the fungus, as far as can be told from the figure without a description, is the species described by Cooke and Peck as *M. pulchra*, and referred by some later writers to the older *M. Alni* (DC.), Winter, which is common especially on *C. alternifolia* and *C. stolonifera*. Certainly, without a differential diagnosis, one cannot suppose that *M. Corni* is other than the well known *Microsphaera* on *Cornus*, whatever view one may hold concerning the perplexing synonymy in this case.

Without stopping to consider other doubtful cases, it will be seen that Dr. Mayr is not well informed in the mycological

literature of the United States; and that being the case, it is to be regretted that he has ventured to introduce into a work, in other respects valuable, so many new names for species of fungi, some of which have for years been well known to American botanists and others of which are doubtful. We can only agree with Von Tubeuf, who, in his review of the present work, *Bot. Centralbl.*, xli., 415, says that "the presentation of new genera and species in the absence of descriptions and adequate figures, the material itself being unripe or imperfect, is not to be approved or acknowledged."

The Golden Flower, Chrysanthemum, is an elaborately illustrated book, lithographed and published by Prang & Company, Boston. The text is not strictly horticultural nor botanical, although much that is interesting in the history of the flower is given. It consists in the main of a collection of verses from various poets, arranged and embellished with original designs by F. Schuyler Matthews, and the whole is illustrated with reproductions of water color studies by James and Sidney Callowhill, Alois Lunzer and Mr. Matthews. The verses have been selected with excellent taste, but the book is meant primarily to be a work of art, in which the national flower of Japan is successfully used in a general scheme of decoration which is Japanese in its motive. Some of the panels in which the poems are set are admirably designed, and Mr. Callowhill has added some of his best floral work in the portraits of the different Chrysanthemums. Of these, eighteen varieties have been selected for their distinctness and decorative qualities, and the reproduction of form and color has been very successfully accomplished. Kioto, one of the famous Neesima collection, is exceptionally well done; Medusa, although not a pleasing flower in our judgment, appears in its most characteristic form, and Lilian Bird, in spite of the fact that no artificial color can equal in delicacy the shrimp pink of the original, will please all who are acquainted with this singularly beautiful flower. Cullingfordii, Mrs. Wheeler and Golden Dragon are also well done, and all the flower portraits are much above the current work of this kind.

Altogether "The Golden Flower" makes a beautiful book for the holiday season, and is most creditable to all concerned in its preparation.

Notes.

According to the *Critic*, Joaquin Miller has abandoned literature for arboriculture, and has already planted more than 20,000 trees on his estate at Oakland, California.

The death, at Nancy, is announced of Antoine Auguste Mathieu, one of the most distinguished students of forests in Europe, formerly Conservator of Forests of France, Assistant Director of the Forest School at Nancy and the author of the well known "Flore Forestière de la France" and of other important scientific works.

Mr. T. S. Brandegee has lately returned to San Francisco from another exploring expedition in the southern extremity of Lower California. He found the season there favorable for botanizing on account of the abundant rains of the past summer, and interesting results from his observation may be looked for in an early issue of the *Proceedings of the California Academy of Science*.

Mr. C. G. Pringle has lately returned to his home in Vermont from a most successful botanical season in Mexico. He brings home with him a collection of 20,000 specimens, and will return again to Mexico as soon as these are distributed. Mr. Pringle's investigations the last year have been largely devoted to the little known region east of San Luis Potosí, where he has discovered many new species, a large proportion being trees and shrubs.

At a horticultural exhibition held in Buda-Pesth last spring a single firm exhibited 1,500 Roses grown in pots, many of them being standards. Among these last was a gigantic *Marechal Niel* which measured ten feet in height and had a symmetrical head loaded with immense blossoms. A committee of ladies was appointed to pronounce upon the most beautiful variety of Rose exhibited, and their verdict gave the first place to Madame Charles Meurice, the second to Merveille de Lyon, and the third and fourth to Baron Adolphe Rothschild and Luciola.

Mr. R. Hector, of Placer County, California, told a convention of fruit growers at Santa Cruz that his famous Cherry-tree had brought him in a gross return of \$1,800 in five years. Last year its yield was 300 ten-pound boxes, and an average

price of \$1.50 a box has been received during five years. The tree is a Black Tartarian, thirty-five years old, sixty feet high, with a trunk which girths more than ten feet at a height of six feet above the ground. It stands in deep, rich sandy loam on bench land near the American River. The ground is irrigated each year immediately after the fruit, which matures very early in the season on account of the warm and sheltered location of the tree, is picked.

Under the heading "*Populus heterophylla*, L.," the editor of the *Bulletin of the Torrey Botanical Club* says: "Another locality for this rare tree in the middle states has been discovered by Rev. L. H. Lighthipe near Woodbridge, Middlesex County, New Jersey. The stations now known for it at the north, besides those given in my 'Catalogue of Plants for New Jersey' and its somewhat wide distribution on Staten Island, are Northport, Long Island, and Guilford, Connecticut, as recorded by Professor Sargent in his Forestry Report in the Tenth Census."

Herbaria were not common two centuries ago. Gibson, whose "Account of Several Gardens near London" was written in 1691, says of a Mr. Darby at Hoxton: "He has but a little garden, but is master of several curious greens that other sale-gardeners want and which he saves from cold and winter weather in greenhouses of his own making. . . . He is very curious in propagating greens, but is dear with them. He has a folio paper book in which he has pasted the leaves and flowers of almost all manner of plants, which make a pretty show and are more instructive than any cuts in herbals."

A correspondent of the *American Garden*, speaking of the many kinds of plants which are used for hedges in our southern states, says that one of the most beautiful for the purpose is the Gardenia or so-called Cape Jessamine. In the South Carolina garden where he saw it, "it flourishes in those parts of the shrubberies which lie on the edges of the Rice-fields, where it is valuable as being a handsome evergreen shrub which can stand water. During the spring freshets the family take to the canoes and are paddled between the rows of Gardenias, which hedge in a favorite walk, and which will emerge as green as ever from their bath of several weeks' duration. Even the smaller plants and cuttings do not object to a submersion which would kill the Magnolia and other native plants."

In his "Notes on England" the historian Taine has well expressed the difference between the type of garden developed in the south of Europe and that which owes its origin to England and has spread through all northern countries. For the inhabitants of the south, he says, a garden has always been a sort of open-air salon, the chief use of which is to provide a pleasant, convenient place for social intercourse. Thus, its formal, architectural design and artistic decoration with fountains, statues and balustrades is eminently appropriate; while, as the peoples of the north look upon a garden as a place in which to escape from men and commune with Nature, they have inevitably developed a style from which regularity and all other evidences of artificiality are banished in favor of arrangements which preserve or simulate the work of Nature herself.

A late bulletin from the New Jersey Experiment Station commends the potash salts as insecticides. It has been observed that farmers who use the muriate or Kainit in Corn-fields as a fertilizer have no trouble from wire-worms, white grubs or the Corn-root louse. Peach-trees have also been successfully planted in lice-infested orchards where all had formerly died by first treating the soil with Kainit. Professor Smith made some experiments of his own which substantiated the opinions of the farmers. He also tried solutions of the muriate and of Kainit for spraying, using one ounce to a pint of water in each case. The spray killed aphides on Wheat-heads and on Rose-bushes, and mealy bugs on greenhouse Camellias. In most cases the plants were uninjured, the Kainit inflicting damage more rarely than the muriate. Without further experiment these salts should be used with caution on foliage; but for underground species of destructive insects they should be tried whenever practicable. They have a high fertilizing value, and will help the plants to overcome insect injury by encouraging their growth as well as by destroying the insects.

Gotthelf Wilhelm Poscharsky, who held an honorable position among the landscape-gardeners of Germany, died recently at Dresden in the seventy-third year of his age. For many years he had been Court-gardener in that city, and to his labors as a cultivator added those of a designer in laying out some of

the gardens attached to the suburban residences of the royal family. In his youth he had studied architecture under the famous Gustav Semper, and this preparation stood him in good stead when he turned his attention to gardening. Before his appointment as Court-gardener he had designed many charming private gardens in the outskirts of the town which now have been swept away to make place for solid lines of buildings. But every visitor to Dresden must remember the splendid avenue of Chestnut-trees which leads from the Neustadt to the Waldschlösschen restaurant, high on the northern bank of the Elb; and this will long remain a monument to Poscharsky, as he planted the trees with his own hands about forty years ago. The beautiful gardens in Chemnitz were also of his creation.

The Boston *Advertiser* asserts that Dr. Hale thinks he has found a possible solution of the mystery which hangs around the origin of the name of Rhode Island. "In his wanderings about the country regions he has found that the Rhododendron grows luxuriantly all over the island in its season, and he queries within himself whether the early settlers may not have made use of this fact in selecting a name for their habitation." It is probable that this curious query originated in the mind of some newspaper hack, rather than in Dr. Hale's. Aside from the fact that the Rhododendron is very rare in all regions north of New York, it is difficult to suppose that men of a turn of mind at once so unscientific and so unpoetic would have named an island after a flower. It is still more difficult than to accept the common theory that they named it from its fancied resemblance in shape to the Island of Rhodes in the Old World. But even in the highly improbable case that a flower inspired the choice of a name, it would more likely have been the Wild Rose, the "Rhoda" of the Greeks, than the Rhododendron or "Tree-rose," since the Wild Rose grows as prolifically in this region as the *Advertiser* asserts to be the case with the Rhododendron, which only grows now in one locality within the state of Rhode Island, namely Worden's Pond, and is not known to have grown at any time on the island of Rhode Island.

The International Agricultural and Forestry Congress, which was held in Vienna during the month of September last, attracted some 1,200 persons. Its most important feature seems to have been an address delivered by Chief Forest-Master Prosper Demontzey, of Paris, on "The Works of Reforestation and Stream Correction which have been undertaken in France since 1860." The speaker was most competent to discuss his subject, having himself been at the head of many of the works in question, and the facts and statistics he gave, as we find them reported in *Gartenflora*, are extremely interesting. To show the damage which may be done by streams which have become what the Germans call "wild" in consequence of the deforestation of the high lands where they rise, he described the catastrophe at St. Pous (Hérault), in September, 1875, when, in a few days, 150 buildings were swept away, more than 100 persons perished, and a damage of over 3,000,000 francs was suffered. Such disasters are now prevented by replanting the high lands, by turfing the banks of the streams, and by regulating with dams the flow of the water. Of course, to accomplish these ends strict and far-reaching legislation, as well as a great outlay of money, has been required. The government has the right to expropriate such lands as it sees fit, and to enforce the execution of needful work by private individuals, assisting them with premiums or subsidies. A certain amount of return for the outlay comes from the land reclaimed from the beds of "wild" streams, which is often admirably adapted to agricultural purposes. During the twenty-eight years covered by the speaker's descriptions (1861-1888) an area amounting to 145,000 acres had been replanted. Sixty thousand six hundred acres of this were state lands, 50,200 acres belonged to communes, and 34,200 to private individuals who had been subsidized by the government. Twelve and a half million francs had been spent in the purchase of lands, and 25,000,000 had been expended in actual work upon these and other government possessions. Six million francs had been paid out in subsidies and 8,000,000 for salaries and other general expenses. Of the 25,000,000 credited to "actual work" on government property over 7,000,000 were spent in planting, about 12,500,000 in controlling streams and more than 5,500,000 on accessory works, such as road and fence building. As a total we see that 51,500,000 francs—more than \$10,000,000—have during twenty-eight years been spent by the French government in partially repairing the damage caused by just such a willful destruction of the forests as is going on to-day, with tenfold greater rapidity than ever in Europe, in almost every part of our own wide land.

Elementary Botany for Young People.

LAST spring a child's paper published in Boston offered a reward to any little one who would collect between the 1st of May and the last of September fifty kinds of native flowers and send in a list of their names. A small boy in Newark, New Jersey, began with flowers of the Dandelion, Chickweed, Violet, Spring Beauty, and some others, found in back-yards and vacant city lots, and then, as his collection halted, his mother accompanied him on a short ride into the country one May afternoon, and the list was increased by the Columbine, Hepatica, Dog-tooth Violet, Azalea, Strawberry, Geranium and several more. This was the beginning of a quest which was kept up with unflagging enthusiasm until the season of Golden Rods and Asters, and now his mother, under the title of "A Memory of Summer," has just published in *The Sunday Call* an entertaining account of the little collector's work. The list numbers less than a hundred, but it is pleasant to learn that the writer now finds herself "associating certain times and places with the finding of certain wild flowers"; but the point of most importance is that the child has begun the study of botany, and has begun it in the field and not in a school-book.

At this age of the world there ought to be no need of explaining how the mental processes employed in the investigation of natural objects which come within the scope of a given science differ from those used in studying a written treatise on the same science. The ordinary method is to place a book before the child and bid him memorize the facts which have been discovered by others. What seems the more natural plan is to encourage him to study the objects themselves, to compare them and classify them—in short, to do exactly the kind of work that the most advanced scientific explorers are engaged in. It ought to be noted, however, that the profoundest investigator is only carrying on in remoter fields the work which every child begins long before he can read or even speak; that is, he is familiarizing himself, by the actual use of his senses, with the objects about him, and making himself systematically acquainted with their qualities. It would seem to be the

part of reason to encourage the exercise of those faculties which give habits of observation and comparison instead of permitting them to grow feeble through disuse during the years of school-life. No doubt it is proper to impart dogmatic information to the young, but it will hardly be urged that this is the chief end of an education. It is certainly worth something to a man to have eyes which do not fail to see the objects that surround him and a mind alert to note their relations and to draw inferences from them; and this is an equipment which the proper study of natural science furnishes.

Bearing in mind that the facts acquired are of less importance than the mental attitude and aptitude encouraged, the science of botany offers unusual advantages for developing the power of systematic observation. The material objects needed for the study are constantly present in infinite variety, abundance and beauty. In the example alluded to at the opening of this article flowers alone are spoken of, and if the sole use made of them was to identify the plants by name the educational value of the summer's collecting was comparatively slight. The naming of the plants is an unimportant matter compared with a study of their points of similarity and contrast and the effort to group them according to their affinities. But the flower is a small part of the plant, and the study need not lag when flowers are gone. Every tree now furnishes obvious characters in its general form, and in the way this form is developed by the peculiar ramification of its branches; in the color and texture of its bark, in the scars which show the arrangement of its leaves, in its spray and winter-buds. Broad leaved evergreens and conifers would furnish leaves if window plants could not be found in every house, and, as Professor Ward has observed, even at this season the nature of a Hyacinth-bulb can be studied in contrast with that of a Potato-tuber, and every nut or apple or orange that a child eats could be made an interesting study under proper guidance.

In short, there is no season when the child cannot make direct personal observations of plants, and when, under a skillful teacher, he cannot be drawn out into an intelligent description of what he sees. Moreover, there are no objects more attractive to the young, more agreeable or convenient to handle or better adapted to close observation and exact description. Professor Marshal Ward brought out these truths with great clearness in an address before the British Association for the Advancement of Science at its late meeting, and in regard to the proper method of teaching elementary observational botany he said :

The teaching of elementary botany to children should commence with the observation of external form, and might well be initiated by a comparative study of the shapes of leaves, the peculiarities of insertion, their appendages, and so on. The point never to be lost sight of is that if you teach a child to discriminate, with the plants in hand and from observation only, between such objects as the simple, heart-shaped, opposite, ex-stipulate stalked leaves of a Lilac, and the compound, pinnate, alternate, stipulate leaves of a Rose, you lay the foundations of a power for obtaining knowledge which is in no way to be measured merely by the amount or kind of information imparted. It does not matter whether the child learns the trivial facts mentioned above, or not, but it is of the highest importance that the child be taught how to obtain knowledge by such direct observation and comparison; and the beauty of it all is that, as is well known, the child will retain most of such information as mere matter of course.

There is one danger to be avoided, however. Young children should not be troubled with the difficulties of theoretical morphology; they should be made familiar with the more obvious roots, stems, leaves, tendrils, thorns, flowers, etc., and not forced to concern themselves with such ideas as that the flower is a modified shoot, the bulb a bud, etc., until they have learned simply to observe and compare accurately. Later on the step must be taken of rousing their minds to the necessity of drawing further conclusions from their comparative observations; but, if the teacher is really capable of teaching, it will be found that the children begin to suggest these conclusions themselves, and, this stage once reached, the success of the method is ensured.

The Beginnings of Fruit-culture in Germany.

AN article published not long ago in the *Illustrierte Gartenzeitung*, of Vienna, gave, on the authority of old state papers, some interesting facts with regard to the fruit-culture of former times in the kingdom of Wurtemberg. It seems that the earliest mention of this industry is found in accounts of the destruction of vineyards and orchards during the wars of the thirteenth and fourteenth centuries, while the first recorded edict for their protection dates from 1515, and imposes a fine on any one who shall cut down fruit-trees, wild or cultivated, on open grounds. Another edict, dated 1552, declares that children caught stealing fruit shall be punished by their fathers, or imprisoned, or put in baskets and dipped in the water. That wild fruits were still largely depended upon is proved by an ordinance of the year 1566, saying that a cultivator may pick up the fruit from wild trees, but must not shake them, as what remains on the branches must be left for the animals which at that period the upper classes so greatly delighted to hunt. It appears that the planting of fruit-trees was not prescribed until about 1600, when the setting out of Mulberry-trees was ordered. Each grown man under the age of forty was to plant one, and each stranger coming to reside in the province was to plant two on public land; and from later edicts it appears that the fruit of such trees could be gathered by the planter during his life-time and then by his widow, but that after her death they reverted to the commune. The edict of 1655, which declared that fruit-trees must not be planted nearer than seven feet and nut-trees not nearer than ten feet to a neighbor's boundary line, still holds good. The Mulberry continued in high honor through the eighteenth century, for we read of an order dated 1755 which prescribes the planting of all new roads with two lines of these trees, standing sixteen feet apart. In the following year Apple and Pear-trees are also named for such service, but merely in positions where Mulberries would not grow or bear. Only in 1792 was heed paid to the fact that the interval between the trees which sufficed for Mulberries was insufficient for the other sorts. Then a distance of twenty-four feet was prescribed for old roads and of thirty-two feet for new ones.

In 1718 a desire to maintain the reputation of the vineyards which produced the then famous Neckar wine, called forth an order against the planting of fruit-trees in vineyards, accompanied by sentence of immediate death against all that had already been thus planted, unless they were over fifty years of age, when they might be preserved until their time of bearing should be over. In 1723 a money reward was offered for the destruction of wasps' nests.

Until the end of the last century there were no nurseries of fruit-trees in Wurtemberg. The first was founded by Duke Charles Eugene when he established the *Karls Akademie* on his estate, "La Solitude," and decided that horticulture should be among the branches taught. The father of the poet Schiller was, after his retirement from the army, for many years director of this horticultural school.

Wine is, of course, mentioned very early in this series of public documents, but only in 1644 does one read of inns where beer as well as wine is sold, and drinks made from other fruits than the grape are not mentioned until 1650. The preparation on a large scale of all such drinks is then forbidden on account of the practice of using them to adulterate wine. It is only permitted to each farmer to prepare a certain stipulated small quantity for the consumption of his own household. Otherwise, it is declared, it would soon be impossible for the poor, and especially for women in childbed, to get their needful draught of pure wine, to say nothing of the ruin that might come on the country at large were this capital industry to deteriorate. A little later even the fabrication of small amounts of cider is forbidden; but it seems to have been impossible to enforce so radical a measure, and there is soon a return to laws which do not prohibit, but strictly control and limit its making. Not until 1735, however, was the sale of cider allowed, and even then the warning against its admixture with wine was reiterated. Sometimes the two beverages could not even be sold at the same time, though cider might be alone. The use of certain inferior kinds of fruit for brewing drinks is also often forbidden even at this late date. Much fruit seems to have been used in those days for cooking purposes, even more, proportionately, than at present, although the Germans are remarkable to-day for their love of this kind of food. Yet cooked preparations of fresh fruit seem to have been almost exclusively employed, for references to dried fruits are few, and the prices named for them in 1622 are so high that they appear to have been then a luxury. These careful and strict regulations, of which we have here quoted only a few among many, prove that the government of that time

took a truly paternal interest in the affairs of private cultivators as well as of the commune as such. But there can be no doubt that such regulations did much to encourage the development of local industries, or, at least, to keep them in the best path that the wisdom of the time could discover. Moreover, they were sometimes in the direction of enlarging, not restricting, the liberty of poor farmers, as is proved by a law of 1567, which gave them the right to transplant young wild fruit-trees from the forests without any payment therefor. This privilege was a greater one than it may seem to modern readers, for there were vastly greater numbers of such trees in the forests then than now; and it was also more of a concession than we can easily realize, for hunting was then the one great amusement of the rich, and not only beasts of the chase were carefully preserved, but likewise the woods wherein they found their food. It should be noted, however, that the permission is given for personal use only; no transplanted tree is to be sold, and it seems as though each peasant were allowed to take but a single tree.

Vancouver's Park.

IN Stanley Park the City of Vancouver has a unique possession. It is in fact a section of the original forest, with all that is venerable and impressive in such an object, connected with a brisk young city, where everything is bright and new. Five years ago not a house stood here, where 15,000 people are now riding in electric motor cars through streets brilliant with electric lights. The city has the best hotel in British Columbia, and one of the most beautiful theatres on the continent, and is in touch with cities east, west and south, and even with Alaska.

In the skurry of growth on our side of the border a park is one of the last things to be thought of. Here it was one of the first. This is because Vancouver is not a mushroom town, but is growing normally and soberly, and without the rush and ruffianism of most new settlements. The wealth of the province in fish, fur, gold, coal, building stone and timber made a town needful hereabout, and the Canadian Pacific Railroad focused it on Burrard Inlet by making that its terminus. The city stands on a peninsula of high and healthy land, with room for metropolitan expansion, and its pleasure-ground covers a second peninsula given off from this, a slightly elevated tract ten miles around. It is encircled by a road; a drive-way and a few corduroy paths have been run across it; at the entrance, which is reached from town by a pretty bridge crossing a salt inlet, there is a bit of lawn and garden, a keeper's cottage and a few cages of native animals—bears, wolves, foxes, badgers, hawks, owls and eagles; but except for these slight changes and additions, and the huts of a score or two of Indians, who enjoy squatters' rights and have not been asked to move on, this reservation is in a state of nature, and it is designed to keep it so, in so far as consists with public use.

An inhabitant of eastern towns finds this park unlike anything that he has seen before. It is covered with forest down to the edge of the sea; indeed, the trees lean above the waves and fall into them in their decay. Burrard Inlet on the east, "the Lions' Gate" on the north and the Georgian Gulf on the west enclose it with ocean water that softens and cools the air, while the spicy fragrance of Cedar enriches it. On the landward side, great mountains, peaked with snow and scarred with avalanches, tower in alpine majesty, and this combination of sea, mountain and forest cannot be matched on our north Atlantic coast. Everything has a luxuriance that suggests a warmer zone, even the kelp in the bay throwing its streamers on the tide to a length of eight fathoms from tip to root, and the trees on shore rising from one to three hundred feet high. These trees are the glory of Vancouver. The height of them is less striking when seen in mass than when seen alone, for the breadth of green detracts from the apparent altitude, just as the width of Niagara Falls has an effect, at first view, of diminishing their height; but when they stand alone, or when a cabin or other familiar object is near enough to offer a standard of comparison, one better appreciates their majesty. I found that the readiest way to guess their height was to imagine one of our sky-scraping New York flats erected beside them, and to mark off with the eye spaces of fifteen or twenty feet, the number of such intervals indicating the number of stories that such a structure would contain. I judged from this crude measurement that the Times and Tribune buildings would be nearly hidden, in many parts of the wood, from the view of a person who was so placed as to look over the tops of the trees.

The Douglas Fir here has its noblest growth, and it is little surpassed by the giant Sequoias of California. Its grace and shapeliness are no less remarkable than its height, for it has a

delicate taper and is as straight as a mast. Indeed, if ships could be fitted here their masts could be "stepped" as solid timbers instead of having the top and top-gallant masts added as separate pieces. A sea captain tells me that he saw a mast taken from one of these trees, on Puget Sound, 104 feet long without a knot or branch in its entire length, while the bark was so thin, as compared with that of the Redwoods, that it gave no trouble to the strippers; and a scientist in Canadian service tells me that he measured one tree that threw its first branch 160 feet above the ground. It is from solid trunks of this tree that the Siwash hew their gondola-like canoes, which in their proportions and evenness of balance would be a credit to any boat-builder in the world. The huge limbs of the Fir give to the avenues of Stanley Park the shadowy solemnity and beauty of cathedral aisles, and the greenish brown moss with which many of them are draped may be compared to moldering banners such as hang from the walls of Henry VII's chapel in Westminster. Walking in these magnificent forest-arches, breathing their sweet air, listening to the mysterious music that the wind is making overhead and feasting on the rich color of the foliage, one feels the same uplifting of spirit that comes in the presence of grand mountain scenery, for the trees seem to be as distinctly types of greatness and endurance as the hills.

While the few deciduous trees that have gained roothold flourish like the evergreens they do not gain so great a size, although Poplars will be found not less than 100 feet in height. It is in the undergrowth, even more than in the trees, that the fatness of the soil and the indulgence of air and rain and sunshine are perceptible, and especially is this true of the Ferns, for the dainty Aspidium of our eastern fallows is here knee-high, and the common road-side Brake is nearly as big as an Elder-bush. Without choosing a particularly large one to measure by, I stood beside one of these plants, and straightening the stem, found that its upper frond was at least seven feet above the ground. One is occasionally startled by the glide of a snake and the whirr of a partridge, but as hunting is forbidden in the park it is not likely that this splendid undergrowth will ever be trodden down. The only thing to dread is that fire may somehow reach the wood, and that such disheartening damage may be wreaked as careless men have wrought among the Selkirks and in the valleys of the Fraser and Columbia, where miles on miles of wood like this have been converted into charred fields dotted with gaunt skeletons of Cedars, Hemlocks, Firs and Spruces. The greatest value of Vancouver's park is that it exhibits a native product at its richest. The illustration on page 635, which shows the wealth of this forest-growth, is taken from a photograph by Notman.

Brooklyn, N. Y.

Charles M. Skinner.

Basket-Work of the North American Indians.—II.

THE conifers contain a certain number of plants of great value to the native basket-maker. The best known is the Great Cedar or Arbor-vitæ (*Thuja gigantea*) of the coast ranges and Cascade Mountains of Oregon and California. This tree has a thin fibrous bark coming off in long ribbons, of which the Indians make mats, bags, baskets and articles of dress. Says Dr. O. T. Mason, in the article already quoted: "Mats, wallets and rectangular baskets are produced by the plainest crossing of alternate strands varying in width from a millimeter to an inch." . . . "Cedar mats of great size, and made with the greatest care, enter as extensively into the daily life of the Indians of this vicinity (coast of British Columbia) as do the buffalo robes into that of the Dakota Indians. They may be seen upon the floors, sleeping berths, before the doors of the houses, and they are also used as sails for their boats and are wrapped around the dead."

The roots of several conifers supply excellent material for the woof of basketry, varying in color from gray to light red and dark brown. The Hoopa and Klamath Indians use the roots of the Bull Pine (*Pinus Sabiniana*), gathering large pieces, sometimes six inches wide, which they prepare by parching in hot sand. The roots of the Spruce (*Picea Engelmanni*, and probably others) are quite tough, and a common basket-material of the north-western Indians. The roots of the Tamarack (*Larix occidentalis*) are used by the Indians on the headwaters of the Yukon River for "basket kettles," which are woven very neatly, and ornamented with hair and dyed porcupine quills. The dye is obtained from "berries and a kind of grass growing in swamps." (Smith's Rep., 1856.)

Pitch is frequently employed by the Indians of the Great Basin of Arizona and New Mexico to render their trays and jars water-tight.

Of the *Liliaceæ*, the Yuccas stand foremost as basket and

textile plants. Their fibrous leaves furnish excellent material to the Apaches, Pimos, Pueblos, etc. The *Yucca filamentosa*, *Y. gloriosa* and *Y. aloifolia* were formerly held in some esteem in the eastern and southern states for the manufacture of string, rope, mats and other household articles. In the great interior arid region, from California to Texas, *Y. baccata* is of decided economic importance. The full grown leaf is three to four feet long, tough and pliable, and yields an excellent textile fibre; when slightly parched in ashes it becomes still more supple, and may be split into strands of various sizes, which are woven into coarse mats and baskets, and otherwise used as whips, withes and rope by Mexicans and Indians. The leaves of the allied species, *Y. filifera* of northern Mexico, are equally good; valuable also for the same purposes are those of *Y. angustifolia*, *Y. elata* and *Y. Whipplei*.

To the same family belongs the *Xerophyllum tenax* of the Pacific coast, a common perennial with numerous radical, narrowly linear leaves two to three feet long. These leaves do not contain textile fibres, but are sufficiently strong and flexible for weaving, and are largely used by the Indians of northern California and Oregon for the white groundwork of their finer grades of basket-work.

Several species of Agave (*A. Americana*, *A. heteracantha*, *A. Sisalina*, etc.) are well known textile plants also, turned to good account by the Indian and Mexican basket-makers.

It will probably be a matter of surprise to most botanists to hear that the leaves of *Iris macrosiphon* are much used in northern California and in Oregon to make ropes, fish-lines, nets and a cloth hardly distinguishable from coarse canvas. I have received interesting specimens showing the various steps of the process. The leaves are one to two feet long and one to three lines wide, each with two strong fibres forming the edges. These fibres are dexterously separated by the squaws with a sharp zinc thumb-piece, then neatly and evenly braided into cord of variable size, or otherwise woven into nets, cloth, etc. The leaves of the Palmetto (*Sabal Palmetto*) yield fine pliable strips, from which are made hats, mats, baskets, etc.; doubtless those of the *S. Mexicana*, which extends northward to the Lower Rio Grande, are used for the same purposes by the Mexicans. Those of the Saw Palmetto (*Serenoa serulata*) are made into hats and baskets by the negroes.

Even the Ferns contribute several useful plants to our list. The Chain-Fern (*Woodwardia radicans*) of the Pacific Coast has long stalks, each containing two fibre-vascular bundles in the shape of large, flattened, brown threads, tough and flexible. While still fresh the stalks are bruised and pounded so as to liberate the threads, which are then cleaned and stained in an infusion of Alder bark. These threads become brittle in drying and must be used moist. Another Fern affording an elegant material for the woof of the nicer caps and baskets of the Hoopa and Klamath Indians is the Maidenhair (*Adiantum pedatum*). The stems are of a deep, lustrous black on one side and red on the other; after being soaked in water or wet with saliva, they are split open with the finger-nail so as to separate the black skin from the unused red side.

The bast of the Lime or Linden-tree (*Tilia Americana*) is exceedingly tough and strong, and readily made into cordage, matting and baskets. The wood and bark of the Leatherwood, a shrub common in the Atlantic States (*Dirca palustris*) and on the Pacific Coast (*D. occidentalis*), have always been extensively used by Indians and settlers. The bark is almost as strong and useful as that of the Lime-tree; the wood is soft, tough and flexible, so that branches can be bent into hoops without breaking. The bark of the Canoe Birch, as everybody knows, is readily and frequently made into jars and baskets in the region of the Great Lakes.

The wood of several hard-wood trees, cut into thin boards, ribbons or shavings, is sufficiently elastic to lend itself to basket-work; that of the White Oak (*Quercus alba*) and of several species of Hickory (*Hicoria*) was formerly much used for this purpose. The soft wood of the White Birch (*Betula populi-folia*), and of other white-wood trees, is still employed along our northern frontier and in many parts of Canada by the descendants of the Algonkins and Iroquois. Thousands of their pretty baskets, wrought into many shapes, are sold in the towns and villages of the northern states.

Rushes, on account of their abundance, softness and pliability, have been more or less used by many tribes. Pretty specimens of Rush basketry, made by the Klamath Indians from undetermined species, are found in the National Museum. The *Juncus effusus*, often a weed in the Atlantic States, is said to be cultivated in Japan for the manufacture of fine floor-mats. The tough scapes of *J. robustus* are split by the Indians of south California and wrought into the material of their baskets.

In the Sedge family we have the common and widespread Bulrush (*Scirpus lacustris*) frequently employed by Indians to make mats, loose baskets, and as thatch for their huts; the var. *occidentalis* or "Tule" of the Pacific Coast, often eight or ten feet high, for these and other purposes is a plant of economic value.

Lastly let us mention the Cat-tail (*Typha latifolia*), whose leaves, twisted together, have, since the colonial days, been used in making chair bottoms. According to Professor Dudley they are now collected quite extensively in central New York for the manufacture of chair-bottoms and baskets.

The Indians have a great fondness for color, and, besides the many shades of the raw material, often use native dyes with excellent effect. The bark of several species of Alder yields, by infusion, a very good coloring matter; this bark, at first grayish white, becomes bright red by exposure. The Hoopa and Klamath Indians use the bark of *Alnus rhombifolia* (perhaps also that of *A. rubra*), the Navajos that of *A. incana*, var. *virescens*, which, says Dr. W. Matthews, U. S. A., they combine with the root bark of *Cercocarpus parvifolius*, using juniper ashes as mordant.

In the Great Basin the black dye used in the ornamentation of baskets is obtained from *Suæda diffusa*. A black dye is also made by the Navajos from the berries of *Rhus aromatica*, var. *trilobata*, by mixing them with ocher and the gum of *Pinus edulis*.

The Spotted Willow-twig Aphis.

OUR various species of Willow are particularly subject to the attack of aphides or plant-lice. No less than nine of these insects have been described as occurring upon them. No part of the tree, unless possibly the roots, is exempt from attack; and the bark and twigs receive the exclusive attention of at least five species. Some of these often become seriously injurious, and more frequently, perhaps, their presence is extremely annoying where they occur upon shade or ornamental trees in private grounds or public parks.

The aphides most commonly found upon Willow-twigs belong to the genus *Melanoxanthus*. Three American species of the genus are known. The Willow-grove Aphis (*M. salicis*) is probably the most abundant in the eastern and middle states. It is very similar in appearance and habits to the nearly related Spotted Willow Aphis (*M. salicis*), which is represented in the accompanying figures. This insect lives over winter in the egg state on the bark of Willow-twigs. Early in spring the eggs hatch into young plant-lice that insert their tiny beaks into the bark of the tender twig and suck out the sap. They grow rapidly, and each one soon becomes the mother of a dozen or more young aphides. Hence these lice are called viviparous. The generation that came from the egg are all wingless, but the young borne by these probably develop into both wingless and winged forms, which are also viviparous. Successive generations continue to appear throughout the entire summer, all being viviparous, and some having wings, while others have none. By midsummer they often have increased so enormously as to cover all the twigs of infested trees, making them appear filthy and unsightly, as well as impairing their vitality by extracting the sap. A single one of the lice hatched

Fig. 83. SPOTTED WILLOW-TWIG APHIS. OVIPAROUS FEMALE. (MAGNIFIED.)

from the egg in spring may become the ancestor of many millions before autumn. But in October a true sexed generation develops, the males being winged and the females wingless. By the union of these the true fecundated egg is obtained.

The egg-laying female is represented at Fig. 83. It is about one-fifth of an inch long, bluish black in color, with a glaucous bloom, and has a distinct white line along the middle of the back. There is also a row of white spots along each side. The honey-tubes or cornicles are bright orange yellow. The

Fig. 84. SPOTTED WILLOW APHIS. WINGED MALE. (MAGNIFIED.)

wingless viviparous female is much like this in general appearance.

The winged male is represented, magnified, at Fig. 84. It is one-fifth of an inch long, with a wing expanse of one-third of an inch. The body is bluish black, with the wings hyaline and their veins yellowish brown.

The egg-laying habits of this insect are peculiar. The oviparous females apparently congregate for the purpose of depos-

Fig. 85. EGGS OF SPOTTED WILLOW-TWIG APHIS.

a, Egg, magnified; b, Eggs and oviparous females on Willow-twig.

iting the eggs in one or a few places on the tree. There they will cover the bark with them, as represented at Fig. 85, b. The egg itself is shown magnified at a of the same figure. It is about one-twentieth of an inch long and oval in form. When first laid it is covered with a liquid which on drying becomes grayish, giving the egg a peculiar appearance. Under the microscope the structure of this gray coating suggests a thin covering of felt.

The artificial remedies ordinarily used for plant-lice are applicable to this species. Kerosene emulsion and whale oil soap are the standard remedies for this class of insects.

Plant Notes.

Some Recent Portraits.

OF the plants figured in the December issue of the *Botanical Magazine*, the number which completes the one hundred and sixteenth annual volume of this, the most venerable of the publications of its class, the most interesting from a garden point of view is the beautiful purple-flowered *Thalictrum Delavayii* (t. 7152), a native of the mountains of Yunnan, and one of the first of the numerous plants discovered by the Abbé Delavay to flower in Europe. It is a slender herb, two or three feet high, with long-petioled, ternately decomposed, radical leaves, triangular in outline, and ten or twelve inches

broad, with wiry, dark purple petioles. The leaflets are a third of an inch broad, obtusely three to five lobed, with a cuneate, rounded or cordate base. The pendulous flowers are pale purple, in very lax panicles, and are borne on long, slender, decurved pedicels. The flowers are an inch across or rather more when expanded, with elliptic-ovate, obtuse ribbed sepals. The affinities of *T. Delavayii* are with *T. Chelidonii*, a native of the Himalayas.

Other plants figured in this issue are *Rhodostachys Andina* (t. 7148), an ornamental Bromeliad inhabiting the Cordilleras of the northern provinces of Chili; *Scaphosepalum pulvinare* (t. 7151), a native of New Granada, and the representative of a small genus of Orchids whose distinctive characters are the superior lip, the free or nearly free dorsal sepal, the lateral sepals connate under the lip, and the strongly recurved upper lip. If we are to judge from the present figure, this plant has little to interest the cultivators of handsome plants; *Arisema fimbriatum* (t. 7150), and *Rhododendron Boothii* (t. 7149), a handsome Bootan species with yellow corolla and conspicuous scarlet stamens, discovered with several other species forty years ago by Booth, who visited India at the instigation of his uncle, Mr. Thomas Nuttall, a familiar and revered name among the cultivators of botanical science in America, for the purpose of collecting seeds of Himalaya Rhododendrons. The editor, Sir Joseph Hooker, adds to his description of this species some interesting remarks on the distribution of the genus, which he believes, judging by the results of botanical explorations recently made in western China, will probably far exceed, in the number of its species, all previous estimates which have been made with regard to it, the discoveries made in the eastern Himalaya being only harbingers of what the vast mountain regions further east may be expected to yield in new forms of Rhododendrons. The genus, which is represented in western Europe by three species only, with two additional in the southern Caucasus, develops remarkably in the Himalaya region from west to east. Four species are found in the western Himalaya, while in Sikkim twenty-nine have been collected. Bootan has twenty-five species, of which seventeen occur also in the Sikkim provinces; but Sir Joseph Hooker believes, "considering how imperfectly that great and lofty province has been explored (its alpine regions not at all) it may safely be assumed that this number does not include half of what it contains." East of Bootan little is known of the vegetation until the borders of China are reached, and here in the western mountains between sixty and seventy species of Rhododendron have already been discovered, although only fragmentary explorations have yet been made; and it is, therefore, not impossible that the Chinese Empire may contain more species of the genus than all the rest of the world besides.

Foreign Correspondence.

London Letter.

WITH the thermometer registering from six to twelve degrees of frost almost daily, and a dense fog which has continued night and day for nearly a fortnight, the difficulties of in-door gardening in the neighborhood of London have been unusually trying lately. Soft-wooded plants, such as Begonias, winter-flowering Acanthads, etc., have been almost denuded of leaves as well as flowers. The only houses in which there is anything like interest are the Orchid-houses, and even here many flowers have suffered from the effects of the fog. Calanthes appear as though they had been boiled; the buds of Phalænopsis have turned yellow and fallen, whilst even such strong flowers as Cypridiums, Dendrobiums and Lælias are affected in color and durability.

VANDA GIGANTEA.—This is a magnificent Orchid, well named both in regard to its foliage and flowers. Flowering at this time of the year it is exceptionally valuable. Its leaves are stout, leathery, a foot and a half long by nearly three inches in width. The raceme is produced near the base of the stem, and is a foot long, as thick as a goose-quill and bears about a dozen flowers. These are composed of five ovate fleshy segments (sepals and petals) almost equal in size and arranged regularly round the small clavate labellum, forming a cup two and a half inches across. Their color is bright cowslip yellow, with blotches of cinnamon; the back of the sepals is tinged with purple. This is a good plant for large tropical houses, as is also its near ally, *V. Batemanni*. According to Griffith *V. gigantea* is a native of Burma, and is usually found on the trunks of *Lagerstræmia Flos-regina*.

CYMBIDIUM TRACEYANUM.—This is a provisional or rather unauthorized name for a remarkable Orchid which has lately

flowered with Mr. Tracey, nurseryman, Twickenham, who exhibited it at the last meeting of the Royal Horticultural Society. It is probably a large flowered variety of *C. Hookerianum*, Reichb., f., as it resembles that species in every character except the size of the flowers. These in *C. Traceyanum* measure five and a half inches across; the sepals are an inch wide, the petals slightly narrower and the lip one and a quarter inches across. In color there appears to be no difference between the flowers of this and of *C. Hookerianum*. Mr. Tracey obtained his plant from an importation of *C. Lowianum*.

There are four recognized species of this section of Cymbidium, all of them natives of the Sikkim Himalayas. They bear a close resemblance to each other—so close that some botanists would not hesitate to unite them as forms of one somewhat variable species. They are *C. giganteum*, *C. Hookerianum*, *C. longifolium* and *C. Lowianum*. The first of this quartette is an old garden plant, but it rarely occurs in cultivation now. It was introduced into England about fifty years ago. The flowers are about three inches across and colored dull green, with brown longitudinal stripes on the sepals and petals, the lip being yellowish, with dark red spots.

C. HOOKERIANUM was introduced and flowered by Messrs. Veitch about the year 1860, but was not named until six years after, when Reichenbach named it in compliment to Sir Joseph Hooker, "with the writer's best wishes as a gratulation for the first new year's day of his Kew directorship." It has broader leaves than *C. giganteum*, and flowers nearly five inches across; the sepals and petals are apple green, with lines of cinnamon brown, the lip and column yellowish white, with numerous purple spots. As already stated, except that the flowers are a little larger, I cannot see how Mr. Tracey's plant differs from this species.

C. LONGIFOLIUM was described by Don, but did not get into English gardens until 1873, when it flowered with the Messrs. Veitch. It differs from the two species already referred to in its narrower leaves, smaller flowers, and in the evenness of the anterior segment of the lip, that organ being crisped in the other two. I have, however, seen it and *C. giganteum* in flower together, and could see no appreciable difference between them in the size, color or form of their flowers. *C. longifolium* is found at an elevation of 6,000 to 7,000 feet on the Sikkim Himalaya.

C. LOWIANUM is the most ornamental of the four, a good variety of it being a really grand plant when well grown and carrying its long spikes of large, lasting flowers. It was introduced by Messrs. Low & Co. in 1877, and described in that year by Reichenbach as *C. giganteum*, var. *Lowianum*, with this reservation: "It may even prove to be a new species, yet I do not dare to speak about this question from the materials actually at hand." Two years afterward the Professor raised it to the rank of a species, and in the same year a fine picture of it was published in the *Gardeners' Chronicle* from a plant flowered in the Clapton Nurseries.

These four, or, including *C. Traceyanum*, five Cymbidiums have long, arching, dark green leaves in tufts, and when well treated they form handsome specimen foliage plants. They are not difficult to flower, and their long, many-flowered spikes are very ornamental, notwithstanding the quiet colors of the flowers. The largest specimen Orchid ever seen in cultivation was a huge plant of *C. Lowianum* exhibited in London by Baron Schroeder last year.

CYPRIPEDIUMS.—There were some interesting hybrid Cypridiums exhibited at the meeting of the Royal Horticultural Society on December 9th. The most beautiful was Messrs. Veitch's *C. Niobe* X, noted by me last year about this time. It is the outcome of a cross between *C. Fairreanum* and *C. Spicerianum*, and both in form and color it is of exceptional merit. Were all hybrids in this genus as attractive as this, one would have nothing but praise for those who raise and distribute them. Unfortunately, good hybrid Cypridiums are the exception, not the rule. If one breeds pigeons or dogs or even cabbages he destroys all the progeny that are inferior to the parents; but a hybrid Cypridium is honored with a name, a picture, a glowing description and often with a big price for no other reason than that it is of hybrid origin. If compared with its parents it very often proves inferior to both as an ornamental plant.

Mr. Sander also exhibited a fine hybrid named *C. Pollettianum* X, interesting as being the offspring of two hybrids—namely, *C. calophyllum* X and *C. wnanthum superbum* X. The last named is a beautiful Orchid, and *C. Pollettianum* is at least its equal in size, form and attractive colors. The dorsal sepal is large, deep port-wine purple running into lines toward the apex, the upper portion being rosy margined with white. The petals are dark purple, almost black, paler about the base,

where there are a few black eye-like spots; the pouch is rich brown-purple. The whole surface of the flower is very glossy. It is a dusky beauty and certainly one of Mr. Sander's best hybrid productions. *C. Castleanum* × also received much attention and was admired by many. It is the production of *C. superbiens* and *C. hirsutissimum*. The flower is large, claret-red, with a shade of purple and small black spots on the lower part of the petals. The lip is like that of a good variety of *C. hirsutissimum*. Mr. Sander is prouder of this than of any of his hybrids.

Other Cypripediums exhibited were *C. insigne longisepalum*, characterized by a long dorsal sepal, otherwise a poor form of a good, useful Orchid; *C. Alcides* × from *C. insigne* and *C. hirsutissimum*, worthless in comparison with its parents; *C. Orpheus* × from *C. venustum* and *C. callosum*, and certainly unworthy of so good a name. A plant called *Silenipedium Weidlicheanum* ×, with *S. Hartwegii* and *S. Schlimii* for its parents, scarcely differs from the old *S. Sedeni*. *C. Maynardi* × is the result of crossing *C. purpuratum* with *C. Spicerianum*, and is not unlike *C. Lathamianum* × described two years ago. The largest flowered hybrid Cypripedium hitherto raised was one shown under the name of *C. Osbornei*, the offspring of *C. Spicerianum* and *C. Harrisianum superbum*. The dorsal sepal is two and a quarter inches by two inches, and white, except toward the base, where it is dull red, a line of the same color extending up the middle to the tip. The petals are three inches long by one inch in width, and the pouch in front two inches long and one and a half inches wide. The color of these parts of the flower is glossy brown-purple. Altogether a remarkable flower.

Cælogyne barbata, with seven flower spikes about eighteen inches long and bearing about forty expanded flowers, deservedly obtained a cultural commendation. The white flowers, with a patch of brown-black on the front lobe of the hairy lip, were pretty as well as being unusual. *Lælia anceps*, bearing about thirty spikes, each with two or three expanded flowers, proved its excellence as a winter blooming Orchid. *L. Tresiderianum* ×, a hybrid from *L. crispa* and *Cattleya Lodigesii*, was represented by a well-flowered specimen, as also were the deep rose-crimson colored *L. Gouldiana* and *Cattleya O'Brieniana*.

Cultural Department.

Fern Notes.

THE multitude of forms and habits to be found among Ferns gives opportunity for displaying their natural graces in a great variety of ways. Some of them, for example, can be very effectively used on pedestals or in baskets for conservatory adornment, and it may be worth while to give a small list of sorts especially adapted to this purpose. The sorts referred to may, as a rule, be readily obtained, and they do not require special attention in order to induce them to grow, they being strong-growing species that are content with reasonable care.

The soil should be an open, well drained mixture, as all vigorous Ferns will enjoy liberal watering, and the temperature should be fifty-five to sixty degrees at night in all cases, although *Woodwardia radicans* and *W. orientalis* do better in a lower temperature, say forty-five to fifty degrees at night, and under these conditions are less liable to the attacks of thrips.

The first to which attention is directed, and certainly one of the most graceful Ferns in cultivation, is *Goniophlebium subauriculatum*, a South Sea-Island species that has long been in cultivation, but yet is not nearly so common as its merits deserve. It has bright green pinnate fronds that sometimes attain a length of eight to twelve feet, and the fronds being freely produced and pendulous in habit, make this plant one of the most striking pedestal ornaments that can be imagined. The sori or fruit-dots of this species are also quite noticeable, being very similar to those of some of the Polypodiums, bright yellow in color and so deeply sunk in the frond as to produce a little protuberance or wart on the upper surface. In fact, the characteristics of the *Goniophlebium* have induced some authorities to class them with the Polypodiums, and the plant in question is frequently labeled *P. subauriculatum*, while it has also been called *Schellolepis subauriculatum*.

Another fine plant of the same family is *Goniophlebium verrucosum*, which is somewhat similar in habit to the preceding, but has broader fronds and pinnæ. *G. verrucosum* is also pendulous, but its fronds seldom exceed four to six feet in length.

Nephrolepis davallioides furcans is a fit companion plant for the foregoing, being so strong and rapid a grower that it forms a perfect fountain of fronds five or six feet long when grown under congenial conditions. This fine plant is a crested form of *N. davallioides*, and is not only extremely handsome as a pedestal or basket plant, but is also one of the most effective varieties for exhibition, while the fronds being of good texture are useful for cutting.

One or two of the stronger Lygodiums may also find a place in our list, notably *L. volubile* and *L. dichotomum*, both of which are fine sorts with large, dark green pinnæ, and the scant habit so well known in the Hartford Fern (*L. palmatum*), the American representative of this genus. *L. volubile* and *L. dichotomum* are both quite strong in growth and evergreen, the fronds continuing to grow until they reach a length of several feet.

Davallia solida will also become a handsome specimen when well treated, and is best suited for basket cultivation. It is a native of the Malay Islands, and produces a strong rhizome, from which issue its dark green fronds, arching in habit and about two feet long.

Woodwardia radicans and *W. orientalis* are both highly ornamental cool-house species, the first being found in portions of Europe, Asia and America, while the latter is also Asiatic, being found in China and Japan. *Woodwardia radicans* has already been described in these columns, but it may be repeated that the fronds are produced from a decumbent rhizome, are three to six feet long, pendulous and dark glossy green in color, and are frequently viviparous.

W. orientalis has much broader fronds than the preceding; but they are not nearly so long, and are usually dotted all over the upper surface with a profusion of young plants.

The Woodwardias may be potted in a somewhat heavier soil than the preceding species with good result, but the drainage should be thorough, as they enjoy an abundance of water, and during the summer are benefited by syringing overhead. Some of the best plants I have seen were grown in a house of Camellias, with which plants they shared the syringing.

Holmesburg, Pa.

W. H. Taplin.

Tuberous Begonias.

THE cultivation of tuberous-rooted Begonias is so easily managed that these beautiful flowers should have a place in every garden as well as in every conservatory. The dry tubers should be obtained early in spring, say in February or March, when they can be had at a very moderate price. It must not be expected that there will be a great percentage of really fine flowers in the cheap kinds, as the best varieties are selected for their superior qualities in color, size and form, and are kept distinct and sold at a dearer rate. Nevertheless, the cheaper varieties are good enough for general bedding if obtained from a reliable source. When an absolute color is desired we must take a named variety of the given shade; but if varying shades are not objected to, then it is as well to get seedlings. The largest tubers are not always the best. Indeed, in my experience with both single and double varieties, I have found that the larger bulbs produced plants of coarser habit, and with foliage and flower lacking some of the finer qualities of those produced from moderate sized tubers. In any case the tubers should be plump and well developed.

The time of starting the roots must depend upon the time when flowers are wanted. If required for early blooming in the greenhouse or window they should be started in gentle heat about the middle of February in an open light position. They should be potted in single pots a little larger than the bulbs, using a soil composed of light loam, sharp sand and leaf mould in about equal parts. Good drainage is an essential in growing Begonias in pots, and when potted they should be placed in a temperature of sixty-five degrees, giving ample ventilation without exposure to cold draughts. The tubers will then seldom fail to grow, no matter where placed on shelves or benches, provided there is sufficient heat. When first potted sufficient water should be given to moisten the soil thoroughly and equally, and this condition of moisture should be maintained, avoiding a sour or sodden soil at any time. When the plants have pushed up two or three leaves and the roots have begun to show themselves around the inside of the pots, they are fit to be potted into larger pots in a compost containing a trifle more loam than that in the smaller pots, and this will promote a sturdier growth.

Plants so started will commence to flower about April and continue to do so throughout the entire summer. If flowers are not wanted before June, March or the 1st of April will be early enough to start the roots. At this time less artificial heat

is required, and the warmth of an ordinary greenhouse will suffice to start them into growth. I always prefer a little heat at starting, whatever the season, as I find they will grow more evenly instead of straggling along one after the other.

and lightly covered with the soil, which is gently pressed together and sprinkled with water enough to moisten it throughout. This moist condition should be carefully maintained and the boxes kept in a gentle hot-bed, where care

A Roadway in Stanley Park, Vancouver.—See page 630

A very satisfactory way to start Begonias in the end of March or April is to plant the tubers in boxes about three inches deep, well drained and in the same compost recommended for pot culture. The bulbs are placed close together

should be taken to avoid a steamy atmosphere, which is likely to occur if sufficient ventilation is not given. Treated in this way they grow into vigorous plants. When they have formed one or two leaves they should be carefully lifted and set in

suitable sized pots, using the same soil as heretofore advised. Peat should never be used when leaf-soil can be obtained; but whatever materials are used they must be open and light, so that water will quickly pass away. With small pots little drainage is required. When potting the soil must not be pressed close. One or two taps on the bench is sufficient, especially for the single varieties. In potting the bulbs into five-inch or six-inch pots the tubers should first be barely covered with soil, and they should be placed as near the glass as possible. If plants for exhibition are desired they will need larger pots, and the shift should be made as soon as the roots touch the sides of the pots, for it is of prime importance that the plants do not become pot-bound; nor should they be allowed to become dry at the bottom, and if this condition should happen a thorough soaking should be given by dipping the pots into a bucket of water. The soil for a shift into seven or eight-inch pots should be heavier than that first used—that is, it should contain a little more loam, to which may be added a little well decayed hot-bed manure. The compost must not be sifted, but used coarse, but well mixed. Nothing like a rank manure must be used. The soil should be made moderately firm. Loose potting and rich soils conduce to a soft and rapid growth which will not flower as well until it has become hardened and matured. It should be always understood that it is of little use to pot plants that have reached their blooming stage. This work must be done before their roots have become matted round the pots.

Any plants required to form large specimens should have a vigorous growth encouraged from the start until they occupy their flowering-pots. They need light, rich soil, with a fair amount of heat and a moist air, with careful ventilation; but a stuffy atmosphere must at all times be avoided, as this will not permit the solid growth which alone gives flowers of the greatest substance and quality. When plants are showing their flowers in the greenhouse they should have a position where the air is constantly passing under and among them, otherwise they will decay or damp off in dull or wet weather. It will be of great benefit to the plants to get once a week a little weak sheep-manure water. When the plants have done flowering, which will be about the middle of October or the beginning of November, water should be withheld entirely so as to ripen the tubers, and this can be easily done by placing the pots on their sides under the stages or some other place out of the reach of frost, where they can remain until they are required again next year. The bulbs will require larger pots to start in by reason of their increased size.

As a bedding plant these tuberous Begonias have no rival. Easy culture, freedom of bloom and neatness of habit commend them to every one. For garden decoration the resting tubers should be procured about the end of March in different colors—crimson, scarlet, rose, pink, yellow and white, or mixed if preferred. The bulbs are best started in small pots in a cold-frame, or they can be started in boxes in windows, giving sufficient ventilation to avoid a spindly growth, and gradually hardened to the outside temperature. When they have formed two or three leaves and are well rooted they are ready for their summer quarters, which will be about the 1st of June. The beds should be prepared as for Geraniums or Coleus. When the plants are set they should for a few days be given a slight shading. A watering with a sprinkler should be given, and repeated often at evening during the dry summer months. A few stakes or light wood branches may be used to support them, as frequently the great weight of the flowers will carry the stems to the ground, and thus disfigure them. Neither rains nor dry, sunny weather affect their abundant bloom, which will continue until frost, when the tubers should be carefully lifted, slightly dried, and placed away in the cellar or on shelves in boxes like Dahlias until required the following season. Year after year they will increase in size and strength, producing finer flowers in greater abundance. The single Begonias can now be obtained at a very moderate price. Good double ones are still dear.

New Rochelle, N. Y.

Henry McCrowe.

Brodiaëas.

THE range of this genus is almost as wide as that of Calochortus. California has most of the species; Oregon, Nevada and Utah have some representatives; northern California is the home of the greater number. A few of the Brodiaëas are sometimes found in sandy soil. *B. terrestris* always is, *B. ixioides* occasionally and *B. laxa* in depauperate specimens. I have also received bulbs of some Brodiaëas unknown to me from the Sage-brush sand of Nevada and Utah. *B. capitata* and *B. (Brevoortia) coccinea* luxuriate in the débris

of loose rock and mould on the hill-sides, and the remaining species are natives of clay soils from light to heavy; *B. stellaris*, *B. congesta*, *B. multiflora* in lighter, and *B. grandiflora*, *B. minor*, *B. laxa*, *B. ixioides* and *B. lactea* on rich clay or "wash" soils. *B. peduncularis* is found in the sand and mould in the beds and along the sides of living streams. All Brodiaëas are lovers of water, while the last named species grows in situations where water is standing or dropping continually during the winter. The finest growth of *B. grandiflora* or *B. ixioides* I have ever seen was where winter streams broke over ledges of large loose rocks. The bulbs were in the rich mould in the interstices and catches, and subject to a drip of water until the blooming season, and after that became dry. On the sunny sides of the deep precipitous cañons, where the loose soil rock and leaves have slid down to the bottom of the slope, often growing on low underbrush, which its flower-stalks overtop, *B. coccinea*, the Vegetable Fire Cracker, grows most luxuriantly. In such situations stalks five feet high, and bearing from fifteen to thirty blossoms, are not unusual. *B. capitata* delights in similar soil, but in a sunny exposure. *Stropholirion Californicum*, or *B. volubilis*, a singular species in which the flower-stalks twine around any supporting object, delights in a soil like that suited to *B. capitata* in underbrush.

So much for natural conditions. I have perfect success with Brodiaëas in shallow boxes, the same as described for Calochortus. For a covering I use clay and chip soil. With *B. grandiflora*, *B. capitata*, *B. coccinea* and *B. stellaris* rich soil scraped from a wood-yard proves excellent covering. With others, clay loam, with various mixtures, with chip soil, have been tried, and the bulbs thrive in all of them. In boxes one will hardly use too much water until the blooming season, when moderate moisture only is required, after which the plants should be dried off. They should be planted shallow—four inches is deep enough—and they need abundant sunlight. Here all are perfectly hardy, and I am satisfied that with slight winter protection they will prove so in the eastern states.

Hardy Plant Notes.

UNTIL the end of November *Trollius Europæus* and *T. Asiaticus* were both flowering and maturing seed in the open border, a fact which should be noted. A perfectly hardy plant that produces useful cut flowers for seven months in the open border, and that only requires a moist soil to make it succeed perfectly, stands a good chance of becoming popular if merit commands success. There is another *Trollius* that is a good garden plant, but its flowering season is short. This is *T. Japonicus*, the flowers of which are of a bright orange and most distinct. Its season of flowering is in early summer along with our native *T. laxus*, which is the *T. Americanus* of European lists and gardens, though it is a pity the name, *T. Americanus*, does not possess priority, since we have *T. Europæus*, *T. Asiaticus*, *T. Japonicus* and *T. Caucasicus*. The *T. laxus* has very little to recommend it as a garden plant. It also has a very short flowering season and then dies down until spring again. There is said to be a white form which occurs rarely, but I have never seen it and cannot say anything as to its merits. *Trollius Europæus* and *T. Asiaticus* are very similar in many respects, the principal distinction to an unbotanical eye being that while *T. Asiaticus* has stems usually unbranched, those of *T. Europæus* are often branched, with several flowers to a stem. The easiest way to get up a stock of *Trollius* is from seed, which must be sown at once so that it may be treated to a good freezing in a cold frame. Every seed will come up in spring, but if not subjected to the freezing seeds of this genus will remain dormant for years, as I have proved several times.

Delphinium Zalil is a most distinct yellow Larkspur. I had well nigh given up in despair of ever having living plants from seed, when I happened upon a fine lot of plants that were raised from seeds in a Massachusetts garden, and this set me thinking, and, thanks to Herr Max Leichtlin, I am now the fortunate possessor of a fine lot of plants raised from seed that germinated in three weeks from the time of sowing. We learn from Herr Leichtlin that seeds of this plant, if not sown at once after being gathered, take a long time to germinate. Seeds of this description, even if they possess vitality when sown, have to run many chances before they germinate. What with overwatering, or the reverse, the washing over of seeds, the growth of moss on the surface of seed-pans, but few seeds germinate, and snails or slugs, with their unerring instinct for pans that contain the choicest plants, often make short work of these; and a season's watching and care are lost. It appears that Monsieur Benary, of Erfurt, has purchased the stock of Herr

Leichtlin's seed, and those who wish to try again should do so through this source. This Larkspur is hardy in Massachusetts, but whether a perennial or biennial has not yet been stated decisively.

It is a matter of surprise to me that American dealers in hardy plants have not yet taken in hand *Phygellus Capensis*. This fine plant is hardy in Britain, where it is common in gardens, as also in other parts of Europe, where it can be obtained easily, and the plant is of the kind that travels well. Inability to endure transportation is a serious obstacle to the introduction of many beautiful plants that are rare in gardens simply for this cause. *Onosma Taurica* is a fair example of this. I was much pleased recently to meet with *Phygellus Capensis*, and to learn that it is hardy in this state with a little protection. It was thriving and flowering freely alongside of *Passiflora incarnata*. *Phygellus Capensis* grows about three feet high. One-half of the plant's stature goes to form a large-branched panicle of bright scarlet flowers, resembling somewhat those of *Pentstemon Torreyi*, and, in a word, the plant has all the merits of this *Pentstemon* without its one fault—namely, a tall habit compared with the strength of its flowering shoots. This *Phygellus* propagates readily from cuttings, and seeds are said to germinate readily also, but such has not been my experience, though it may have been that the seeds had lost their germinating power. However, cuttings root readily in about three weeks, and this may possibly be the best way to increase the plant. Even should this plant not prove hardy, it is a desirable one on account of its long flowering season, which lasts nearly all summer. While one possesses but a limited number of these plants it would be perhaps better to lift and store them in a cellar or other suitable place until their hardiness in particularly cold localities has been tested and satisfactorily proved.

The Forest.

Some Vermont Forests.

THE numerous stumps of large Pine-trees and long stretches of stump fences still remaining in many portions of Vermont testify to an original supply of fine timber, such as exists now, if at all, in very small patches. The coniferous trees which are used for lumber—Spruce, Pine and Hemlock—are fast disappearing. Indeed, the fine first growth of Pine timber is already a thing of the past here. Among the mountains remote from railroads some fine Spruce lumber is still standing, but even in these retreats great inroads are being made. One needs only to compare the condition of a few such localities in their present condition with what they were ten or twelve years ago to comprehend what is going on. Twelve years ago the Spruce timber in the immediate vicinity of Mount Mansfield had not been touched, or at least only on its outskirts. On both sides of this grand mountain noble forests were standing. On the Stowe side, between the north end of Mansfield and Mount Sterling, which lies to the east, is what is called Smugglers' Notch—a wild cut between the two mountains on both sides of which are high jagged cliffs. Under and among these may be found flourishing in their season such rare boreal and alpine plants as have tempted many botanists to make long journeys to this spot for the purpose of seeing and collecting them in their natural home. At that time the road to this notch from the south led through nearly four miles of unbroken woods. The mountain slopes on both sides were covered with timber, a large part of which was fine first-growth Spruce. The carriage road leading to the summit of Mount Mansfield from the Stowe side also passed through much good timber. Several miles south of Mansfield is what is called Nebraska Notch, another wild pass through the mountain chain, with bare cliffs on the north and a sloping forest south. For miles east of this stretched a dark Spruce forest, perhaps as fine as the Green Mountains could afford.

Ten years have destroyed much of the beauty of these localities. A steam mill, located near the south end of Smugglers' Notch, has wrought much of this destruction; but on both sides of the mountain well up toward the summit, or as far as the timber of marketable size extends, and eastward of the Nebraska Notch, the Spruce-timber large enough for use has been cut, and much of it at a very small profit I am told. This seems probable, for it is fifteen miles to the nearest railroad station from most of it.

Another interesting locality was at Willoughby Lake. Here was a beautiful sheet of water, pure and cool, between two mountains, with its shores, especially on the west, embraced by a fine first growth timber. There was a remoteness and seclusion about this place that seemed to defy intrusion. This

was the condition of Willoughby in 1878. Since that time the woods have been invaded, the little lake turned into a mill-pond, and the stamp of general desolation which lumbermen usually leave behind them is written on nearly every feature of this once beautiful spot.

The same thing is going on in other portions of the state. The large steam mill at North Stratford, New Hampshire, is fed, I believe, from the forests of north-eastern Vermont. The large quantities of saw-logs which in their season cover the Connecticut River above Wells River do not all come from New Hampshire.

The time is not far distant when Vermont will hardly be able to show within her borders a fair sample of her once abundant mountain forests.

Correspondence.

The Nomenclature of American Grapes.

To the Editor of GARDEN AND FOREST :

Sir.—I send you the result of some inquiries concerning Vahlenberg's *V. palmata* which seems to settle in this country (it has already been settled in France, where American Grapes are most diligently studied) the dispute as to which name should be used, *V. rubra*, Mx., or *V. palmata*, Vahl., to designate the species of Grape which was rediscovered by H. Eggert on the Mississippi River above St. Louis in 1882, and which Dr. Engelmann, in the Bushberg Catalogue, 1883, claimed to identify as Vahl's *V. palmata*, which he so classified, and which was illustrated for the first time in the July, 1889, GARDEN AND FOREST, under Engelmann's name, *V. palmata*.

In the January number, 1884, of *La Vigne Américaine*, published in France, J. E. Planchon, referring to Engelmann's use of *V. palmata*, reviewed all the evidence then at command bearing upon the subject (pages 15-20). I make here a few extracts from Planchon's article: "Sous le nom de *Vitis palmata*, le botaniste danois Vahl. a décrit, en 1794, dans ses *Symbolæ botanicæ* (3^e partie, p. 42), une vigne qu'il avait reçue du Jardin des Plantes de Paris et à laquelle il consacre l'article suivant que je traduis du latin en français," etc. After Vahl's description as translated by Planchon the latter remarks: "Une description aussi incomplète, ne comprenant ni les fleurs, ni le fruit, devait laisser des doutes sur la détermination de cette plante. Aussi l'a-t-on rapportée souvent comme synonyme à d'autres espèces, par exemple au *Riparia* de Michaux, à l'*Estivalis* du même auteur, ou même au *Labrusca* de Linné."

From the above it appears that Vahlenberg obtained the plant he described so incompletely from the Jardin des Plantes in Paris. This plant it appears had several synonyms, such as *V. Virginiana*, *V. Virginica* and *V. Virginensis* (see Planchon's article, pp. 16 and 17). Finally, in summing up the whole matter, Planchon says (p. 20) that the evidence "me confirme tout à fait dans l'idée que le *Vitis rubra*, Michaux, est distinct du *Palmata*, Vahl."

This decision from such an eminent ampelographer as J. E. Planchon should of itself be sufficient; but to make doubly certain, I wrote to Professor Pierre Viala, who was for years associated with Planchon, who three years ago visited this country on a special commission from the French government to investigate the native Grapes of the United States, who since that time has published the completest works upon our species extant, and who this year spent six months in Paris as a specialist in Viticulture for the French government to investigate the plant in question, in the Garden of Plants, Paris, and let me know whether it is the true *V. rubra* of Michaux or not; and here is his reply, dated November 11th, 1890:

"Le *V. palmata* de Vahlenberg du Jardin des Plantes de Paris est un *V. riparia*, et non le vrai *V. rubra*, de Michaux."

Hence we have in synonymy *V. rubra*, Mx.; Syn., *V. palmata*, Englund, Bushberg Catlg., 1883, and GARDEN AND FOREST, July, 1889; *V. riparia*, Mx.; Syn., *V. palmata*, Vahl. So *V. palmata* must not be used except as a synonym.

It will be remembered that in an article of mine published in GARDEN AND FOREST for October 1st *V. palmata* was substituted where I had written *V. rubra*.

Denison, Texas.

T. V. Munson.

[The question raised is one as to the weight of authorities. Dr. Engelmann, a very careful student, had no doubt that Michaux's *Vitis rubra* was identical with the older *V. palmata* of Vahl (not Vahlenberg). Planchon, on the other hand, thought that he had reason to believe that Vahl's plant was a form of *V. riparia*. We have never seen the

article quoted by Mr. Munson, but Planchon, in his revision of the order in De Candolle's "Monographiæ," makes *V. palmata*, Vahl, a variety of *V. riparia*, and while he keeps *V. rubra* distinct, he expresses a strong doubt whether it is anything more than another variety of the same species. Viala, of course, follows Planchon. Whether *V. cordifolia*, *V. riparia* and *V. rubra* should not all be grouped in one species is a matter to be determined by future study in the field by skilled systematists. This, however, does not touch the question in point, which is simply whose judgment ought to be followed, that of Engelmann or Planchon, as to the identity of Michaux's species with Vahl's *V. palmata*. We have preferred to follow Dr. Engelmann.—Ed.]

Clematis Paniculata.

To the Editor of GARDEN AND FOREST :

Sir.—Allow me to add one more note to those which have already appeared in GARDEN AND FOREST as to the beauty and value of this species, and it cannot be too highly commended, as probably the best of the small white flowered kinds. A grafted plant of mine has made a growth of ten feet this season, with numerous shoots which in early September were topped with long garlands of dainty, fragrant flowers borne in great profusion. But what is perhaps the most interesting phase of the plant does not seem to have been insisted on as it deserves, namely, its beauty in early winter. Its thick, leathery leaves proved to be very persistent, and in early November commenced to be touched with bright red and coppery tints, which, as the season advanced, changed to deeper ones, and now, in mid-December, the vine is a mass of dull bronze, over which hover gracefully a profusion of seeds of a deep, clear red, each furnished with a feathery tuft. The scarcity of foliage in the garden at this dull season makes valuable any plant with persistent foliage, even if of no value during the summer; but here we have a plant attractive in every season, and of very peculiar beauty, when most other things have entirely disappeared.

Elizabeth, N. J.

J. N. G.

Recent Publications.

We have been favored with advance sheets of portions of the *Report of the Pennsylvania State Board of Agriculture*. The report of the Botanist, Mr. Thomas Meehan, is always interesting, and from it we take the following extract:

The correspondence of this Department has been for the most part confined to answering inquiries as to the names of plants—some of them being of weeds that have for the first time attracted attention. None of these have, however, been new to the state; nor does it appear that any noxious weeds are spreading more than usual. Inquiries are sometimes made as to the best method of destroying troublesome weeds. No plant can live if it is not permitted to make green leaves. If the land is full of something troublesome there is nothing better than to put it in Corn, and insist on continuous culture—not leaving the work till the weed to be destroyed has thrown out strong green leaves, but before it has had the chance to make any. Occasionally reports come to the Botanist that weeds were not killed by this process. Failure could only come from neglect to hoe or cultivate until the weed enemy has made some strong green leaves. It is a good lesson for a young farmer to give him some stubborn weed-plant—a Canada Thistle or Horse-nettle, for instance—and let him try the experiment.

In like manner it is wholly healthy foliage that will give full crops. Whenever grain loses its leaves before the ears mature the crop is lessened. An excellent lesson can be had from two hills of Corn. Commence to denude the plant of foliage before the silk or tassel forms, and watch the result on the crop. Even those who believe they understand the value of attention to these matters will be surprised with the force of lessons like these.

It has recently been placed beyond all doubt that the continual injury to the foliage of the Strawberry by the work of a Fungus, which spots the leaves, is what proves the continual degeneracy of varieties. The hundreds of new varieties of Strawberries that have been introduced during the past quarter of a century have not given us in any respect better kinds than we then had, but they take the place of kinds that degenerate. When half the leaf-blades are destroyed by the spot, the plant has only half the leaf surface it should have, and suf-

fers proportionately. New seedlings are usually several years old before they get the spot. The Sharpless is said to have resisted the attack longer than any other. The methods of culture, necessary though they be, lower vital power to resist the spot. It is said that the Strawberry in its wild state is able to resist the spot.

Another instance of the value of foliage is illustrated by the early fall of the leaf on the Pear or other trees, from the leaf Fungus, from caterpillars or from other causes. It is well known that the fruit will not then ripen well.

Perhaps one of the best illustrations is by the loss of leaves on the Potato-plant by the Colorado beetle, when all know no crop is returned to us.

It is impossible for a plant to continue long without healthy leaves. We can turn this principle to good account in the destruction of weeds, and to good account also by doing all we can to keep the foliage healthy in the crops we grow.

Professor N. L. Britton, of Columbia College, has recently reprinted from the *Annals of the New York Academy of Science* his "List of the State and Local Floras of the United States and British America." It forms a complete index of works relating to the geographical distribution of our plants, and includes the titles of 791 treatises although all such minor ones as isolated notes and "short lists of observations" have been excluded. The works are divided into four classes: Lists in which exact localities are not given, those giving stations, those in which the mention of stations notes or occasional descriptions are added, and descriptive lists properly so called. The order of arrangement is, however, by countries, states and counties, the class to which each work belongs being indicated by the annexed letter A, B, C or D. The earliest local list of American plants seems to have been John Bannister's "Catalogue of Plants," which relates to the large region then called Virginia and was issued in London in 1668. Next came another Virginian catalogue, published at Leyden by Johannes Clayton between 1739 and 1743. The plants of Orange County, New York, were described by Cadwallader Colden in 1749-1753, and in 1785 the Rev. M. Cutler, of Boston, published a list of New England plants. To-day 106 catalogues instruct us with regard to New England, while 121 refer to the middle states and the District of Columbia and sixty-six to the Pacific coast. These are the largest numbers attached to any of the districts into which Mr. Britton divides the continent, if we except British America, which, considered as a whole, furnishes 123 catalogues, with ten in addition that refer to the explorations of the Transcontinental Survey. But, of course, such division into districts is more or less arbitrary, and it is more interesting to note which individual states have been most diligently studied and described. New York heads the roll with sixty-five catalogues, then comes California with forty-eight, and then Massachusetts with forty-five, Pennsylvania with thirty and Ohio with twenty-eight. The labor involved in the preparation of this little bibliography must have been considerable, and it should meet with a grateful welcome not only from students bent upon personal improvement, but from librarians anxious to make the local departments of botanical libraries as complete as possible.

Horticulture in Canada.

Meeting of the Ontario Fruit Growers' Association.

AT the first session of the annual meeting of the Fruit Growers' Association of Ontario, held a fortnight ago, Mr. A. M. Smith, the retiring President, delivered an address from which we make the following extracts:

Within twenty years the membership of the Society has grown from 30 to 2,100, so that it is now the largest body devoted to horticulture in America and perhaps the largest in the world. Thirty years ago berries were brought to market in pans and pails dipped out with hands or ladles into measures as buyers called for them, and, as a consequence, they were delivered mostly in the form of jam. Apples, pears and even peaches, when not too soft, were marketed in grain-sacks, jolted over rough roads in lumber-wagons, instead of being shipped as all kinds of fruit now are with careful handling and in attractive packages.

Notwithstanding the discouragements of the year the fruit crops on the whole have been as successful as any of the agricultural crops. This season has proved that it is not wise for one whose income is from fruit to depend altogether on one kind. Those who have taken their chances with apples or peaches alone find themselves in a bad position, while those

who have raised many kinds of fruits have found something to fall back upon. Many members of our Association have been doing good work this year by visiting various farmers' institutes and taking part in discussions on horticultural topics and imparting whatever information they could, relating to fruit growing. This is a patriotic and philanthropic work and it should be encouraged.

At the general Fruit Growers' Convention held during the year agents of the various transportation companies were present and gave an attentive hearing to our suggestions and grievances. They manifested a desire to furnish us with better facilities and greater dispatch in shipping fruits, and since the meeting there has been an improvement in this matter. Express companies, however, do not furnish proper accommodations, because they should have shelves in their cars on which to store the fruit, instead of piling the light baskets upon one another in such a way that the fruit is in very bad condition when it reaches the consumer. The pilfering of fruit from baskets and other packages in transport has reached annoying proportions. Almost every shipper is at some time accused of giving short weight or measure, the reason being that after the packages have been shipped they are broken into on the road and a considerable fraction of the fruit abstracted by employes or their friends. The loss is small in each case, so that the shipper does not care to report it, and if he does he gets no satisfaction; but in the aggregate it amounts to a serious tax upon the growers. There is no reason why fruit should not be as safe in a basket in the charge of an express company as money or any other article of value. We have hopes of checking this evil, because we find that transportation companies feel inclined to listen to our united demands; and this is one of the great values of such an organization.

Notwithstanding the advanced position of fruit-growing in this province, it is a fact that not one farmer in ten produces half enough for his own use, and this is true of even the most prosperous ones. It is surprising that in thriving agricultural communities there is so little horticultural taste and knowledge even where there are good buildings, blooded live stock and fine crops; we see no orchards, no small fruits, no flowers, no ornamental planting, and if there is any, it is in such a neglected state that it emphasizes the fact that horticulture is an unappreciated art. Perhaps a diet in which fruit formed a larger proportion would give us a more healthy set of men than one in which fat pork abounds, and if farmers would take a keener interest in surrounding their homes with beauty they would have less complaint to make of their children for emigrating to other countries and engaging in other pursuits.

Professor Saunders is doing a great work in producing new varieties of fruits adapted to the colder portions of our country, and his experiments in hybridizing Strawberries, Raspberries, Gooseberries, Currants and other fruits will prove of great benefit. I saw some of the results of his labors, in testing not a few, but hundreds of varieties of Raspberries, during their season, which had been produced by hybridizing and careful selecting.

Mr. Pettit, in a strong speech, urged that if the foreign fruit trade was to be made profitable, there should be certain market days at centres of traffic where the products of the grower could be disposed of directly to the buyer, and subject to inspection by an officer of the Government, as is the case with cattle, grain, etc. It is essential that grades of fruit should be established, so that a Government brand upon a package of apples or other fruit marked Number one should mean that it was of fair size and color, free from scab and worms, and packed properly in packages of standard size. In the same way grade Number two should have a specific meaning, and in all cases it should be understood that fruit for export should be properly packed. A few consignments of fruit in bad order gives a prejudice against the entire output of the region from which it came. Even where growers are honest in packing their fruits, if there is no standard there will be no evenness of quality, and nothing but strict rules, thorough inspection and accurate grading will give the buyer any guarantee or the grower any assurance that his Number one fruit is not a different article from the Number one fruit of his neighbor. After some discussion the following resolution was passed: Resolved, That we deem it the best interest of the fruit-growers, shippers and consumers, as well as the good name of our country, that a standard of excellence be established for such fruits as are shipped in barrels and other closed packages into the markets of our cities and towns and for transportation to foreign countries, and the Government is hereby petitioned to appoint proper inspectors for that purpose.

Professor Craig, in speaking of the method of the propaga-

tion of fruit-trees, said that while fruit-growers are busily engaged in looking for new varieties, few of them are studying how to improve old methods of propagating the varieties we have, or investigating the effect of the different modes of propagation upon the health and longevity of the subjects. That a tree makes a vigorous growth for three years in a nursery-row is no proof that it will make a valuable orchard-tree, and the reason is not always that the soil and climate are uncongenial. We should know whether the cion is married into a congenial family. The practice of grafting on pieces of roots, which originated in 1811 with Andrew Knight, has introduced many knotty problems into pomology which are still far from solution. Trees grafted on piece-roots allow of deep setting and encourage roots from the cion, and it would therefore seem that in warm climates, where there is no such thing as root-killing, budded trees would be more satisfactory; but in cold climates the piece-roots serve an indispensable purpose where hardness is desired, because they allow the use of the deeply set cion. In this way the piece-roots serve only a temporary purpose, while the cion represents a variety of known hardness. Seedling stock is variable, and only an occasional tree will prove sufficiently hardy to withstand severe climates. Good trees for all purposes can be obtained by using only the first and second cuts from the root, and these should be not less than three and a half inches in length, and the cion between five and six inches.

Pear-trees are almost always propagated by budding, but some firms in the United States are making a specialty of crown grafting on the whole roots. Russian varieties treated in this way and planted eight years ago on the farm of the late Mr. Charles Gibb are now making vigorous growth.

In a recent bulletin, Professor Budd, in discussing the stock for Cherries, mentions the Wild Red Cherries, *Prunus Pennsylvanica* and *Prunus pumila*, as two promising stocks. Of the first, he says that "it has been found that it unites perfectly with all varieties tried on Morellos, Dukes and Heart Cherries, either by grafting or budding. It sprouts, but when top-worked with vigorous sorts it does not appear to have any reserve material to waste in sprouts." Of the second Cherry, he says "as yet its use is experimental, but it unites well with all hardy sorts in budding, and it does not dwarf the parts worked upon it to a greater extent during the first five years than does the Mahaleb." I have tried both these stocks in a small way, but have not been sufficiently successful yet to justify my advocating their use.

In propagating the Plum the same objection to the Myrobalan stock can be urged as in the case of tender stocks for Pears and Apples. The native Plum of the east cannot be recommended, as it is affected by the Black Knot and it grows slowly. The western forms of the same species have not these defects and they unite well when budded or grafted with the Plum, the Peach and the Apricot. These western Plums grow readily from pits, and make large enough stock for budding in August of the same year they are planted. The art of grafting is of immense service, but I have little doubt that trees on their own roots would be, as a rule, less liable to disease.

The best and simplest protection for Roses in winter, according to Mr. James Webster, of Hamilton, has been found to be the mounding up of earth to the height of ten inches about the plant. This mound is removed in the spring when danger of frost is passed, and then the pruning is done. Not more than six or eight inches of wood is left on the strongest Roses, while from the less vigorous ones the weakest shoots are taken away entirely. The wood cut off in pruning is immediately burned, as by this means the thrips and insects which leave eggs in the wood to pass the winter are kept down.

In regard to the use of wood-ashes in orchards, Professor James, of the Guelph Experimental Station, said a fruit-tree makes three demands upon the soil—(1) for the wood, (2) for the leaves, (3) for the fruit. Ashes contain the elements which a tree uses to form healthy wood, and therefore they are useful as a fertilizer for this purpose. Leaves, by the time they fall, have returned their best parts to the tree; but still some loss occurs where the leaves are blown away. In the fruit the orchard sustains its loss mainly, and if we know the constituent parts of this we can tell just what elements are needed. Potash is the largest ash-element in all fruits, and therefore the best fertilizer will contain potash, and that is why wood-ashes are so valuable. Ashes, besides, have some phosphoric acid and lime elements which help to raise their value up to twenty or twenty-five cents a bushel, but when ashes can be had at ten cents a bushel they are the cheapest fertilizer that can be obtained. A complete fertilizer for an acre of orchard would be forty bushels of ashes, 100 pounds of crushed bone and 100 pounds of sulphate of ammonia.

To the question, Does it pay to prune Plum-trees? Mr. Willard answered that for some years he had been in the habit of cutting off from one-half to one-third of the season's growth during the mild weather in the winter when the wood was not frozen hard, and he was well satisfied that it was profitable. On varieties which make a long, rampant growth there is much breakage when the limbs are set full of fruit. By cutting back, short branches are forced out, which gives more fruiting surface and a stronger tree. He does not prune after the trees have begun to grow.

Notes.

The *Eschscholtzia* has been chosen as California's state flower.

The Proceedings of the eleventh annual meeting of the Society for the Promotion of Agricultural Science, held at Indianapolis, make a pamphlet of 125 pages. By the constitution of this association the number of its members can never exceed fifty, but these are the leading investigators in this country in the various sciences related to agriculture. This report contains the latest fruits of study and experiment in this wide field.

Secretary Woolverton, of the Ontario Fruit-Growers' Association, reported at the late meeting of that body that Mr. E. D. Arnaud, of Annapolis, had sent him samples of the fruit of a Cherry-tree which had been picked in September. The fruit is about the size and shape of the Kentish, and of a deep red color when ripe. It has firm flesh and agreeable flavor and bears transportation well. We should be glad to know more of this late-blooming Cherry, which is called the Clark.

Mr. Felix Oswald, writing of southern Mexico in the *Open Court*, says that "on the markets of Vera Cruz and Tampico vegetable products sufficient to support a family of five persons for a day can be bought for one real (twelve cents)." As meat, food and warm clothing are not required in that climate, and as "from the coast up to an elevation of 4,000 feet fuel for the purposes of house warming can be dispensed with for eleven months in the year," it is easy to understand that laborers can support a family on wages which, in northern lands, would not suffice to keep them individually from starvation.

The *Bulletin of the Torrey Botanical Club* for December, 1890, says: "After an absence of two years in South America, during which time he has collected a very large and valuable representation of the plants of that region, Dr. Morong has returned in health and safety. All botanists will bid him cordial welcome, both on his safe return and his entry upon a new sphere of usefulness and activity. The trustees of Columbia College have appointed him to be Curator of their herbarium, a position which has not been occupied since the death of Mr. P. V. LeRoy. In this appointment an important step has been made in the progress of American systematic botany."

Many persons must have wondered at the meaning of the word "*ha-ha*," still often used in England for a sunken fosse. Walpole's explanation is that when dividing walls were first abandoned, together with many other devices of the formal style of gardening, and ditches were substituted, the attempt "was then deemed so astonishing that the common people called them *Ha! Ha!* to express their surprise at finding a sudden and unperceived check to their walks." Modern dictionaries assert that the word is a mere reduplication of *haw*, a hedge, and can be written *haw-haw* or *ha-ha*. As the *ha-ha* is, however, a ditch not bordered by a hedge, but designed to be invisible, this derivation seems as unsatisfactory as Walpole's seems far-fetched.

Young Bamboo shoots, when tender, are eaten as a pot-herb, and to preserve their tenderness they are covered over with earthen pots to blanch them. That this food was in use among the ancient Aryans is evident from the prohibitions of eating the same by the three upper classes of the Hindoos. Green Bamboo shoots are used by the Nepaulese very generally as a pickle, which they prepare by cutting the shoot into small slices and steeping the same in water in a close earthen jar, where they ferment and generate a sort of acetic acid. This preparation is called *Tambi* in Nepaul. It is a favorite pickle both of the rich and poor, and pieces of the Nepaulese round Capsicums, called *Khorasani*, are thrown into the same.

A correspondent of *The North-western Lumberman* calls attention to the interesting fact that about seven-eighths of all the

spools used in the world are produced in Maine and New Hampshire, or are made from lumber manufactured and shipped from those states. Millions of feet are sent every year to the great thread works of J. & P. Coats at Paisley, Scotland, the greatest establishment of its kind in the world, alone. No material for a spool has yet been found as good as the wood of the Canoe Birch. Attempts have been made to make spools of glass and from wood-pulp, but they have not proved successful. A few years ago Birch-land was considered almost worthless in northern New England; now it is held at as high prices, when situated near railroads, as Pine-land. The extension of the Canadian Pacific Railroad into northern Maine is said to have brought a large amount of Birch-timber within easy access of the mills.

The Report of the annual meeting of American Cemetery Superintendents at Boston last August contains much that is of permanent value. A sketch of the life of Adolph Strauch, by Mr. Eurich, of Toledo, is a deserved tribute to the man who originated the so-called "Lawn-System" which has done so much to encourage what is natural in the planning and planting of cemeteries. The essay by Mr. G. Troup, of Buffalo, on cemetery roadways is worthy of study by every one who is interested in road-construction. Mr. Simonds, Superintendent of Graceland Cemetery, in Chicago, read a paper on the trees and shrubs which have proved most valuable in that climate; and Mr. A. W. Blaine, of Detroit, in discussing "Mistakes in Cemeteries," touched upon many common errors in design and maintenance. It is a misfortune that the essay of Mr. J. G. Barker, of Forest Hills Cemetery, Jamaica Plain, which was distributed at this meeting, could not have been included in the Report. Mr. Barker's paper was read before the Massachusetts Horticultural Society, and it contains descriptions of several of the most interesting cemeteries of the country.

The ugly and dilapidated board fence which has surrounded Mount Morris Park, in Harlem, is being torn down, and will be replaced by a fine retaining wall of stone, surmounted by an iron railing. The improvement was desirable, for, although almost unknown to inhabitants of the lower parts of our city, this is certainly the prettiest of all the small parks in New York, and is very probably the most individual park of its size in the world. About two-thirds of its area (which includes two city blocks) is level ground, charmingly laid out with wide lawns, unbroken by cross paths, and with encircling walks flanked by good trees and beautiful groups of shrubs. But in the south-east corner of the park the ground rises suddenly to form a rocky hill higher than the tops of the surrounding houses, which is covered with great old trees, chiefly Oaks. Such an isolated hill rising amid streets which are perfectly level, is a most unexpected feature to find in the heart of a great city, and its harmonious contrast with the flat lawns around it is extremely picturesque. We advise our city readers to use one of the first days when the trees next begin to bud for an excursion to Mount Morris Park, certain that they will feel themselves rewarded, and will wonder why its singularity and beauty are not matters of more general knowledge.

A writer in the *Bulletin of the Torrey Botanical Club*, reviewing Dr. Schweinfurth's recently published work called "*Sur certains Rapports entre l'Arabie Heureuse et l'ancienne Egypte*," the conclusions of which are based on an Arabian journey during which the author collected 920 species of plants, cites the following interesting facts: "The ancient Egyptians cultivated certain trees, dedicated to certain divinities, and among them were the *Persea* of the ancient Greeks (*Mimusops Schimperii*) and the Sycamore; the leaves and fruit of both trees having been frequently found in ancient tombs, where they had been deposited as offerings. The '*Persea*' (not to be confounded with *Persea gratissima*, Gaertn.) has for centuries disappeared from Egypt, but the Sycamore is still found there in large quantities, though only in cultivation. The region of the Upper Nile, rich as it is in Fig-tree species having characteristics that bring them into close relation to the Sycamore, has not as yet shown any in a wild state that might be considered its ancestor. Dr. Schweinfurth gathering from Forskal's notes that in Arabia were to be found species allied to the Egyptian Sycamore, was especially interested in searching for them, and learned that the Fig-tree known as '*Chanès*' in the mountains and as '*Bourra*' on the plains, is identical with the Egyptian tree which incontestably has its origin there. He also found the '*Persea*' growing wild and called '*Lebbakh*,' a term used by the Arab geographers of the middle ages, and which to-day in Egypt is applied to an *Acacia* introduced from India (*Albizia Lebbek*), and which is now, as '*Lebbakh*,' a widespread road-side tree."
